Item 3. SUMMARY

In 2012, the geological team of Niobec Inc., a subsidiary of IAMGOLD Corporation Inc., acted as the operator of the Rare Earth Elements (REE) exploration project. The exploration program results and the mineral resources performed on the REE zone are published in a Technical Report complying with the National Instrument 43-101. The authors of the report are Louis Grenier, Geo. and Jean-François Tremblay, Geo. respectively exploration geologist and senior geologist at Niobec mine site. Réjean Sirois, P.Eng., of G. Mining Services Inc. undertook the role of Qualified Person for the work program and the current mineral resource estimate. All data sources come from the surface drilling done in 2011 and 2012, the underground drilling (S-3607) and the historical data since 1968, time of the discovery.

The Niobec property, which contains the REE zone in a carbonatite complex (St Honoré carbonatite complex), is located thirteen kilometres North of Ville de Saguenay (Chicoutimi), in the limits of the municipality of Saint-Honoré, in the Simard Township, Quebec. This property, held 100% by Niobec Inc., consists of 2 mining leases and 179 claims for 8,010.85 ha. An agreement dated August 31st, 2011 between Niobec Inc. and IAMGOLD granted to IAMGOLD 100% of the beneficial rights to all the non-niobium mineral rights located on the property (including the rights to the REE's).

The St-Honoré carbonatite complex (SHCC) was discovered by SOQUEM (“Société Québécoise d’Exploration Minière”) in 1967. The SHCC is host in a Precambrian rocks (the Saguenay-Lac-St-Jean anorthosite complex) belonging to the Grenville orogenic province of the Canadian Shield (Figure. 3).

This annular intrusive mass, which is almost completely covered by the Trenton limestone of Paleozoic age, is elliptical in planview. The North-East major axial lengthen approximately 3 kilometres and the intrusive covered a surface of about 8 km². Dated by Potassium-Argon (K-Ar) to be 650 my old, the SHCC is part of the igneous alkaline activity related to a tectonic extension event known as Lapetan rift system of the end of Precambrian.

This Alkaline complex is composed of a central carbonatite core, surrounded by an alkaline syenite, a feldspathoid bearing syenite and syenitic foidites (Ijolites and Urtites). The Grenville basement, constituted in this area by pyroxene syenites, Diorites (with hypersthene or magnetite), syeno-diorite with aegyrine and pyroxene gneiss, is highly fenitized near the contact with the SHCC.

The carbonatite core comprises concentric lenses of calcitites (Sovites) and dolomitites (rauhaugites), interpreted as cones sheets and ring dykes. These units consist of a series of crescentic lenses of carbonatite with compositions younging progressively inwards from calcitite through dolomitite to ferro-carbonatite. The massive to brecciated ferrocarbonatite, which form the central core, contains the REE mineralization, mainly as REE

fluorocarbonates and monazite. The mineralization is disseminated between the dolomite crystal phase in the massive facies or form part of the breccia cement in the brecciated facies. REE mineralization is associated with hematite, chlorite, ferroan dolomite, minor thorite, ilmenorutile and pyrite.

The property has been explored since its discovery in 1967 by SOQUEM and SOQUEM & Associates until 1986. Approximately 3500 metres of diamond drill holes have been realized on the REE Zone. The REE mineralization and its economic aspects were identified.

In 2011, IAMGOLD CORPORATION undertook a first 13,798 m drill reconnaissance campaign (29 drill holes) to a depth of 400 m. Added to the SOQUEM drill holes, a first resource estimation of 466.8 million tonnes at a grade of 1.65% total rare earth oxides (TREO) was reported by P.J. Lafleur Geo-Conseil Inc., in March 2012. In 2012, exploration and definition drilling added 23, 851 m (33 drill holes) and tested the REE zone to a depth of 1,200 m.

The drill program conducted by the company on the REE zone aimed to define the three dimensional geometry of the REE zone, upgrade some inferred into indicated resources, extend the inferred resources to the depth of 700 m, provide samples for metallurgical test work and increased the REE mineralization knowledge. The drill program was completed on a 100 by 100 metres grid down to 400 m and on a 100 by 200 metres grid down to 700 m. Three holes exceeded 1,000 metres in total length, and reach a maximum length of 1,337 metres. The two deepest holes demonstrated that the REE zone persists uninterrupted at depth, although the resource model is reported only to a depth of 700 metres below surface.

Based on these new drilling results, a resource estimate was prepared by Réjean Sirois, Eng., an independent Qualified Person, Vice President, Geology & Resources at G. Mining Services Inc., Brossard, Quebec. The REE resource corresponds to an enriched zone of Light REEs (LREE) which is characteristic of this annular carbonatite type. LREEs comprise 98.1% of the weight of the Total REEs (TREE), with the remaining 1.9% Heavy REEs (HREE) that could potentially add significant economic value. The REE zone is estimated at **531.4 Million Tonnes of Indicated resources at an average grade of 1.64% Total Rare Earth Oxides (TREO) and an Inferred Resources of 527.2 Million Tonnes at an average grade of 1.83% TREO**, to an approximately depth of 700 metres below surface (the surface lies at a reference elevation of 10,000 metres).

Item 4. INTRODUCTION AND TERMS OF REFERENCE

This report was prepared by the Niobec mine site geological team and summarized the 2012 works conducted on the Rare Earth Elements exploration project for IAMGOLD Corporation. The surface diamond drilling exploration program was realised about 1 km North of the underground Niobec mine activities, St-Honoré, Quebec. Based on the mining and the metallurgical knowledge, the exploration focused on delimiting and characterizing the rare earth elements mineralized zone while defining and increasing the mineral resources.

Geological data in this report comes from different sources. Over the 35 years of mining at Niobec, internal documents (internal Gems database, internal report, MRNFQ GM filed, historical maps and drilling data, etc.), provided numerous information to the geology department. All the references are available in the Item 23. This report is the results of a compilation and interpretation of the geological description and the geochemical analysis of thirty three new surface diamond drill holes completed in 2012 in a well-known geological environment.

The main authors of the report are M Louis Grenier, Geo. and M Jean-François-Tremblay, Geo., respectively exploration geologist and senior geologist for IAMGOLD on Niobec site. Both supervised all the REEs exploration project operation, conducted by Niobec employees and specialized contractors on mine site, and are responsible for the Item 7 to 26 (property, geology and data), except Item 18 and 19, of the report. Pierre Pelletier, Eng. and Vice-president metallurgy at IAMGOLD, contributed to Item 18 (processing) and Réjean Sirois, Eng., Vice President Geology and Resources at G. Mining Services Inc. is responsible for the Item 19 (resources). Marie-France Bugnon, P.Geo., General manager Exploration for IAMGOLD and Steve Thivierge, Eng. Special projets and geology Superintendent at Niobec contributed to the overall edition of the report. All six persons above are qualified persons (QP) according to the NI 43-101 guidelines.

Item 5. RELIANCE ON OTHER EXPERTS

5.1 Other Data Source

The technical material considered in the present report is based on the existing data produced by IAMGOLD. This material includes a technical report complying with the NI 43-101 published in 2009, 2011 and 2012 relating to the Niobec mine, a technical report complying with the NI 43-101 published in 2012 relating to the REEs zone and various other technical reports regarding the St-Honoré Carbonatite Complex hosting the niobium and REEs depots. Item 23 provides a full list of reference documents used in preparing this report. In the production of this NI 43-101 technical report, the authors has relied on the data collected essentially by new drilling on the REEs zone in 2011-2012 and by producing an updated compilation of geological data.

5.2 Limited Responsibility of the Authors

The authors responsibility are limited to using the data collected by IAMGOLD, assuming it is the best data available to perform this compilation of the REEs zone. The authors do not take any responsibility for the quality of the data that was historically produced by IAMGOLD, other than the customary verification done to comply with the NI 43-101 rules.

The authors responsibility are limited to making a statement about the mineral resources estimation based on the original data and by applying the best method to create its models. There is no mine plan to estimate the mineral reserves at this stage.

The authors had found the quality of the data to be in good standing. There is no reason to doubt or further investigate its validity based on the evidence available at the time of writing this report. The present report intends to comply with the NI 43-101 rules regarding the production of a Technical Report.

The authors are acting as technical experts in the area of geology and mining only. They has limited legal or financial expertise applied to exploration and mining.

5.3 Reasonable data verification

The authors did verify the data available to them for inconsistencies and database entry errors and applied standard statistical methods commonly used in the exploration and mining industry to characterize the data. Topographic plans, mine plans and maps showing the property limits were used to determine the volume of resources available, but the authors did not verify completely the source of information or the legal status of the property, including the rights to own, explore and extract ore material from the site. The authors are not aware of the existence of any claims on the property due to financial grievances (bankruptcy, mortgage, debts, etc.), liabilities or responsibilities due to environment rules, policies or claims to impeach the development of the project.

The authors' knowledge of the region satisfied that the geographic, topographic and geologic information used in this report is correct. The results and opinions expressed in this report are dependent on the accuracy of the geological and legal information's mentioned above, which are up to date and complete at the date of publication of the report. It is understood that no information susceptible to influence the conclusion of the present report were withheld from the study. The authors assert the right, but not the obligation, to modify this report and its conclusions if new information is presented after the date of publication.

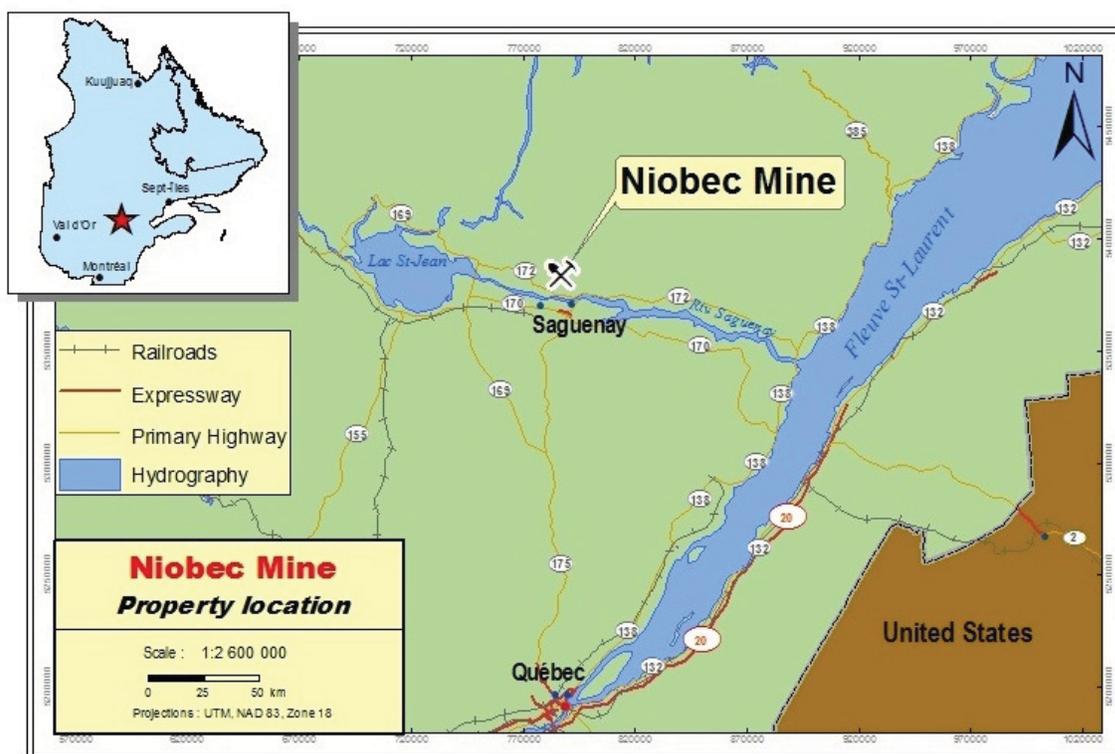

Item 6. PROPERTY DESCRIPTION AND LOCATION

This item 6 is partially summarized from the NI43-101 of February 2009 and March 2011, after validation for the mining titles status from the "Ministère des Ressources naturelles et de la Faune" (MRNF. Web site: www.mrn.gouv.qc.ca).

6.1 Property location

The Niobec property, which contains the REE Zone and the Niobec mine, is located thirteen kilometres north of Ville de Saguenay (Chicoutimi), in the limits of the municipality of St-Honoré, in Simard Township, Quebec (Figure 1).

Figure 1: Niobec property location

6.2 Property description

The Niobec property is held 100% by Niobec Inc., a wholly-owned subsidiary of IAMGOLD Corporation.

The Niobec mine is located on a property of 8,010.85 hectares comprising two mining leases, No 663 and 706 (with surface area of 79.9 and 49.5 hectares respectively), and 179 claims totaling 7,881.4 hectares. The property was enlarged in 2010 with the acquisition of all rights into 23 claims. In 2011 and 2012, for the purpose of the Niobec Expansion project, 113 new claims were acquired principally on the North and the West area of the mining leases. The mining leases have been renewed until 2015 (Figure 2). At the end of December 2012, four claims were suspended because they were under a new mining leases request at the MRNF.

6.3 Mining titles status

Table 1 describes the Claims and Leases of the Niobec Property, with their location shown on Figure 2. This information was taken from the Quebec Ministry of Natural Resources website <http://www.mrnf.gouv.qc.ca/mines/titres/titres-gestim.jsp>, with the registration certificates received by the company and validated by the authors as of December 2012.

Table 1: Mining titles status. (Property Claims = CDC and CL; Mining leases = BM)

NTS Sheet	Type of title	Title no.	Status	Registration date	Expiry date	Surface (Ha)	Registered owner (name, number and percentage)

Item 7. ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

This item 7 is from NI43-101 Technical Report Niobec Mine 2009 (Belzile E., 2009).

7.1 Accessibility

The Niobec mine is readily accessible by existing paved roads and benefits from available water supply and electric power supply sources. The Niobec mine facilities include a head frame, a pyrochlore-to-niobium pentoxide (Nb₂O₅) concentrator, a concentrate-to ferroniobium converter and ancillary surface installations.

7.2 Local Resources and Infrastructures

Niobec mine is close to Ville de Saguenay with a population of about 150,000. The city is serviced several times a day by regional airlines from Montreal. It is about a two hours' drive to Quebec City and five hours to Montreal. Schools (up to University), Hospitals, Governmental services, suppliers and manpower are all available in Ville de Saguenay and at some villages in the vicinity.

7.3 Climate and Physiography

Topography is relatively flat in the vicinity of the mine with an average altitude of 144 metres above sea level. The mine is surrounded by a mix of forest and farms.

The climate of Ville de Saguenay area is temperate with warm summers and cold winters. The mean annual temperature is 2.3°C, with average daily temperatures ranging from -16.1°C in January to +18.1°C in July. The average total annual precipitation is 951 mm, peaking in July (123 mm) and at a minimum in February (51 mm). Snow falls from October to April, with most occurring between November and March. Peak snowfall occurs in December, averaging 82 cm (equivalent to 67 mm of water).

The information is based on data collected at the Bagotville meteorological station between 1971 and 2000, as reported by the CRIACC (www.CRIACC.qc.ca).

Item 8. HISTORY

Following a regional airborne radiometric survey in search for uranium in 1967, Soquem (Société Québécoise d'Exploration Minière) detected a high-intensity radiometric anomaly near St-Honoré, Quebec (Vallée and al., 1969).

Detailed exploration confirmed the radiometric anomaly (high value of thorium and presence of REE) and revealed a carbonate rock locally poor in REE and radioactive elements. The association of these features with a large roughly circular magnetic anomaly suggested the existence of a large carbonatite and alkaline rock intrusive complex. This anomaly was centered on the core of the complex, now referred to as the REE Zone, and a second radiometric anomaly on the syenite intrusive outcropping through the limestones, southeast of the carbonatite (Vallée and al., 1969).

Magnetic and radiometric anomalies were outlined by geophysical prospecting and, subsequently drilled to delineate two zones of economic concentrations of niobium and one REE enrichment zone.

In 1970, Copperfield Mining joined Soquem to explore and develop this project. Twenty one kilometres of diamond drill holes were realized until 1973 to recognize and delineate the two niobium zones. In parallel, five short drill holes (“Série 700” of REE Zone) totaling 706 metres have been realized between 1968 and 1970 on the Central radiometric and magnetic anomaly allowing the discovery of REE mineralization, grading 1.87% REO¹.

In 1974, after 700 bench scale tests, 11 months of pilot plant operation and worldwide market research, a joint decision was taken to initiate the development of 1500 t/day, Niobium mine and mill, under the management of Teck Corporation. The construction was completed in early 1976 both on time and within budget.

In 1975, parallel to the Niobium mine development, 8 drill holes (“Série 800”) totaling about 958 metres realized on the central core allowed to recognize the REE Zone, particularly in its north-east part. The recognized REE mineralization gives an average of 5973 ppm in Lanthanides, equivalent to 2.8% TREO².

In 1978, 2 drill holes touched the southern edge of the REE Zone (total of 672 metres) while Soquem was drill testing some exploration targets at the scale of the carbonatite.

In 1985, three deep drill holes (“Série 85”) totaling 1566 metres have been realized with the aim to extend the recognition on the whole central core, to locate a mineralization with coarser grains of lanthanide and to draw-up a detailed inventory of the various element of

¹ In 1970, Vallée & Dubuc reported only 3 drillholes and 328 metres of drilling for that period.

² In 1986, Dénomme & al reported only 6 drillholes over 585 metres averaging 0.69% La₂O₃ for 1975.

lanthanides. This campaign allowed to define a depth limit of 60m for the hematitic weathered facies, to outline lanthanide rich zones (>2%) in the central part and to recognize the same lanthanides mineralogy and grain size down below the weathered hematitic facies (Bastnaesite and monazite in fine needles or in reddish brown-purple accumulations) (Dénomme & al, 1986).

In 1986, Cambior Inc. acquired the Soquem share in the mine and in 2001 Teck Corporation sold their interest to Mazarin Inc. of Quebec City. In December 2003, Sequoia Minerals Inc. was created as the result of a corporate reorganization of the Mazarin Inc. operations whereby the metal and industrial minerals segment (niobium, dolomite and graphite) became a separate corporation (Sequoia).

In 2004, Sequoia Minerals Inc. shareholders voted in favor of a takeover offer by Cambior Inc., clearing the way for the company to take full ownership of North America's only niobium mine.

In September 2006, IAMGOLD Corporation and Cambior announced their merge to create a new entity. IAMGOLD Corporation Inc. owns 100% of the Niobec mine since November 2006.

In September 2011, Niobec Inc., a 100% IAMGOLD Corporation owned company, is created. Niobec Inc. is the operator of Niobec mine and the owner of the beneficial right of the niobium mineral. In August 31st, an agreement between Niobec Inc. and IAMGOLD granted to IAMGOLD 100% of the beneficial rights to all the non-niobium mineral rights located on the property (including the rights to the REE's).

In 2011, after a long quiet period, REEs became in short supply and prices reached historic highs. A new economic interest for the REE Zone by IAMGOLD-Niobec Inc. boosted the exploration interest by the realization of a first drilling campaign of 29 drill holes totaling 13,798 metres to evaluate the REE resources.

In 2012, the exploration program is pursued. A total of 33 new drill holes for 23,851 metres help defined the three dimensional REEs mineralisation geometry, transform the 2011 inferred resources into indicated resources, extend the inferred resources to the depth of 700 m, provide samples for metallurgical test work and increased the REE mineralization knowledge.

Table 2: Previous exploration drilling, Niobec property.

Year	Area	Total Holes	Total Metres	Hole numbers	Comments
1967	REE Zone	2	54.86	B802-701, B802-702	First holes on the surface Rare Earth Elements discovery
1968	REE Zone & Niobec deposit	14	2,291	782-701 ext, 782-703 to 715	Follow-up on the REE Zone & discovery of the Niobec deposit

Item 9. GEOLOGICAL SETTING

9.1 Regional Geology

The Saguenay region is mainly composed of Precambrian rocks (Figure. 3) belonging to the Grenville orogenic province of the Canadian Shield (Roy, 1977; Laurin and Sharma, 1975; Jooste, 1958; Denis, 1937). The metamorphism reached the upper amphibolite facies-granulite and at least three generations of folds are superimposed. More recently, the Grenville province was divided three distinct lithostructural units (modified from Belzile, 2009):

- The first Unit constitutes a gneiss complex that is divided in three Groups (Groups I, II and III) based on increasing structural complexity from the youngest to the oldest Group. All the rocks from the Group I have been migmatized and deformed during the Hudsonian Orogeny (1,735 million years ago).
- The second Unit is represented by anorthosite and charnockite-mangerite batholiths showing well preserved igneous structures and textures. Anorthosite which range from pre- to post Grenvillian age, are regarded as evidence of crustal extension, the Neohelikian extensional tectonics, which continued during the Grenville Orogeny,

935 million years ago. The mangerites are believed to have been generated by partial melting of the lower crust by the anorthosite bodies, and forms the host rocks of the St-Honoré carbonatite complex.

- The third Unit is characterized by calc-alkaline intrusions that cross-cut the host rocks. The mineralogy of these intrusions is of superior amphibolite facies. At the beginning of the Palaeozoic (or end of the Precambrian), a younger episode of rifting, south of the Neohelikian rift, referred to as the Lapetan Rift System, resulted in the development of the St-Lawrence River rift system (Figure 4). This tectonic extension event incorporated normal faulting, updoming and igneous alkaline activity (Kumarapeli, 1974), including emplacement of the St-Honoré carbonatite.

The St-Honore carbonatite is dated by Potassium-Argon (K-Ar) to be 650 million years old (Vallée and al., 1969).

Figure 3: St-Honoré carbonatite complex and regional geology (modified from Belzile, 2008)

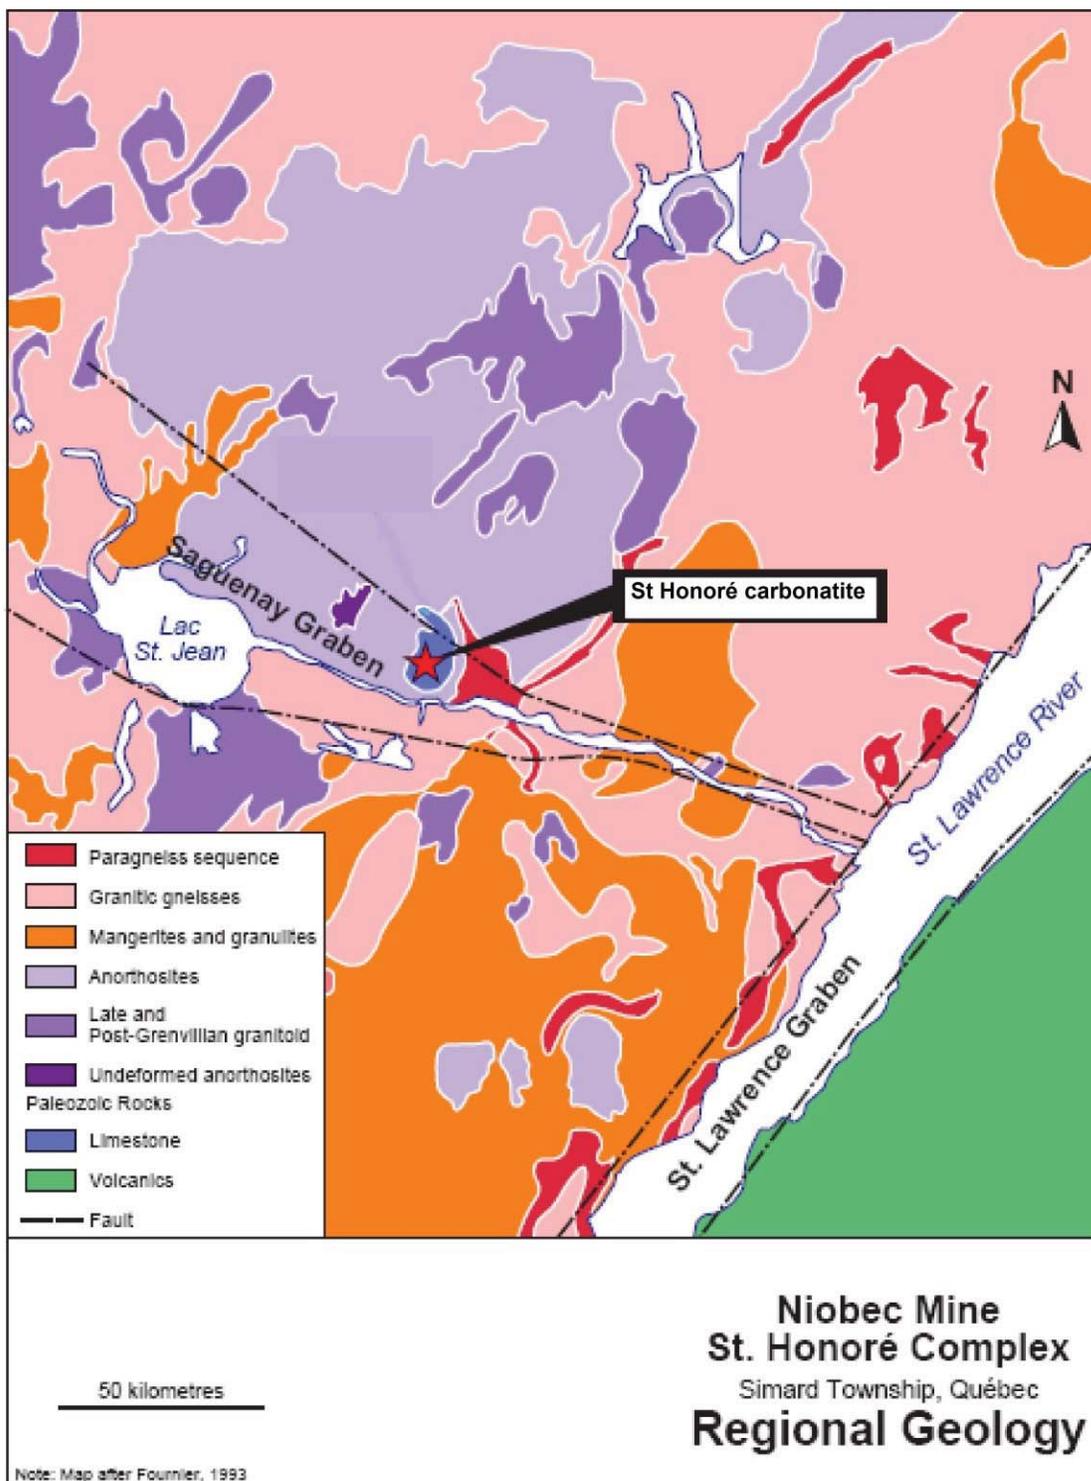

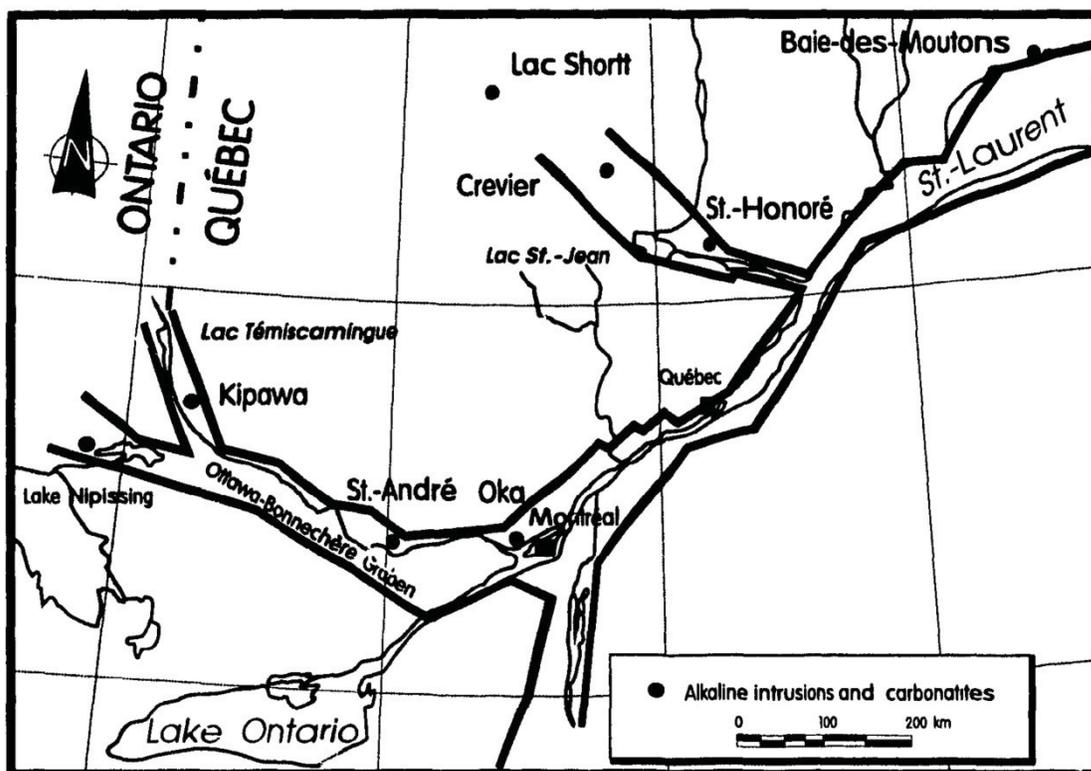

Figure 4: The Lapetan rift system (Fournier, 1993)

9.2 Property Geology

The St.-Honoré alkaline complex is located 13 km NW of Chicoutimi and 5 km West of the town of St.-Honoré. Only few areas of outcrops have been mapped and the intrusive mass is almost completely covered by flat-lying Trenton limestone of Paleozoic age. The core carbonatite intrusion can be interpreted by its regional low magnetic signature and confirmed by numerous exploration drill holes. The intrusion is elliptical in planview, with a north-east major axial length of approximately four kilometres and a surface of about 25 square kilometres.

This alkaline complex intrudes the Grenville basement constituted in this area by pyroxene syenites, diorites (with hypersthene or magnetite), syeno-diorite with aegyrine and pyroxene gneiss (Fortin, 1977).

Carbonatization of the country rocks is interpreted to be a metasomatic alteration product related to the carbonatite complex intrusion (Fortin 1977). This Fenitization is evident from the occurrences of sodic-amphiboles and aegyrine in the host rock, and associated green and red carbonates veinlets (Fortin, 1977).

This carbonatite is known as the host of two individual deposits:

- Niobium deposit in the south part of the carbonatite, which constitute the principal Niobec mine;
- REE Zone mineralized in lanthanides elements, located in the central part of the carbonatite.

9.2.1 *The St-Honoré alkaline complex*

9.2.1.1 Geological Highlights

The first complete geological map, using the different geophysical surveys and drill holes data realized between 1967 and 1975, has been produced by Soquem geologists (Gauthier.A and al.) in 1978. This map, based on petrographic and geochemical studies which allow the definition of the different carbonatite terms (Fortin, 1977), has been actualized and reinterpreted in 1986 by Niobec Mine geology staff using the additional drill holes data realized by Soquem in 1985.

The geological compilation map of Figure 5 is the result of a synthesis of these entire maps and the drill holes data since 1967.

The Alkaline complex is composed by a central carbonatite core, surrounded by mainly an alkaline syenite, a feldspathoid bearing syenite and syenitic foidites (Ijolites and urtites) (Fortin, 1977; Figure 5). The contact of this complex with the country rocks is marked by a phlogopite calcitite in the northern part and in the southern part by the presence of a cancrinite bearing syenite (Dénomme, 1986).

A chronology has been established for this Alkaline complex as follow from older to younger (Fortin, 1977):

Ijolite - Urtite - Foidites syenite – Feldspathoid syenite – Alkaline syenite – Lamprophyre - Carbonatite

Following a petrographic and geochemical study (Fortin, 1977) of different drill holes cores realized in the carbonatite by Soquem (Gagnon and al., 1973), different carbonatite units with different geochemical characteristics have been established. Four Sovites (Calcitites) types and three Rauhaugites (dolomitites) types have been recognized and constitute the different units of the carbonatite core. These units consist of a series of crescent shape lenses of carbonatite with younger compositions progressively inwards from calcitite through dolomitite to ferro-carbonatite (Fortin, 1997). This evolution is attested by the numerous xenolithes of the alkali syenite rocks in the carbonate at the scale complex and at a smaller scale between the different carbonates facies themselves.

9.2.1.2 St-Honoré Carbonatite Complex Geometry

The St-Honoré carbonatite complex is composed by a central carbonatite core, surrounded by mainly an alkaline syenite, a feldspathoid bearing syenite and syenitic foidites (Ijolites and urtites), where the elliptical carbonatite core is oriented mainly northeast-southwest (Fortin, 1977). From the center to the periphery (Figure 5), this core includes (Modified from Fortin, 1977):

- An eccentric core of brecciated dolomitite and ankeritite (C1), containing up to 4.5% total rare-earth elements as Cerium, Lanthanum, Neodymium, Praseodymium and Europium in fine-grained fluorocarbonates minerals (Bastnaesite, Synchisite and Parasite (Fournier, 1993),
- Two low REE and niobium dolomitite in small masses north and south of the brecciated core (C2) and probably a cone sheet of a syenite (S1) to the west,
- Ring dyke of a low-grade niobium and rare-earth dolomitite (C5) in the north, east and west part,
- Cone sheet of a high-grade niobium (>0.4% Nb₂O) white to pink dolomitites with apatite and magnetite in the southern sector (C3) enclosing a mega-xenolith of syenite in its southern limit,
- Cone sheet of pink dolomitites and calcitites (C5'), with high grade niobium mineralization, magnetite, phlogopite and apatite,
- Cone sheet of a barren red feldspathic dolomitite (C9) south of the mine area (C5),
- A cone-sheet of phlogopite calcitite at the northern extremity, with disseminated apatite (C4),
- A cone sheet of pyroxene calcitite, with disseminated apatite in variable thickness, at the southern limit of the core (C6),
- A circular outer ring containing feldspathic and feldspathoidal alkaline rocks mainly syenite (S1), urtite and ijolite,
- A triangular mass of cancrinite (Na-Ca-Al-silicate and carbonate mineral) and garnet syenite encountered at the extreme southeast part of the complex (S2).

Figure 5: Geological compilation map of the St-Honoré Carbonatite Complex (modified from Soquem map 1978 and Niobec map 1986).

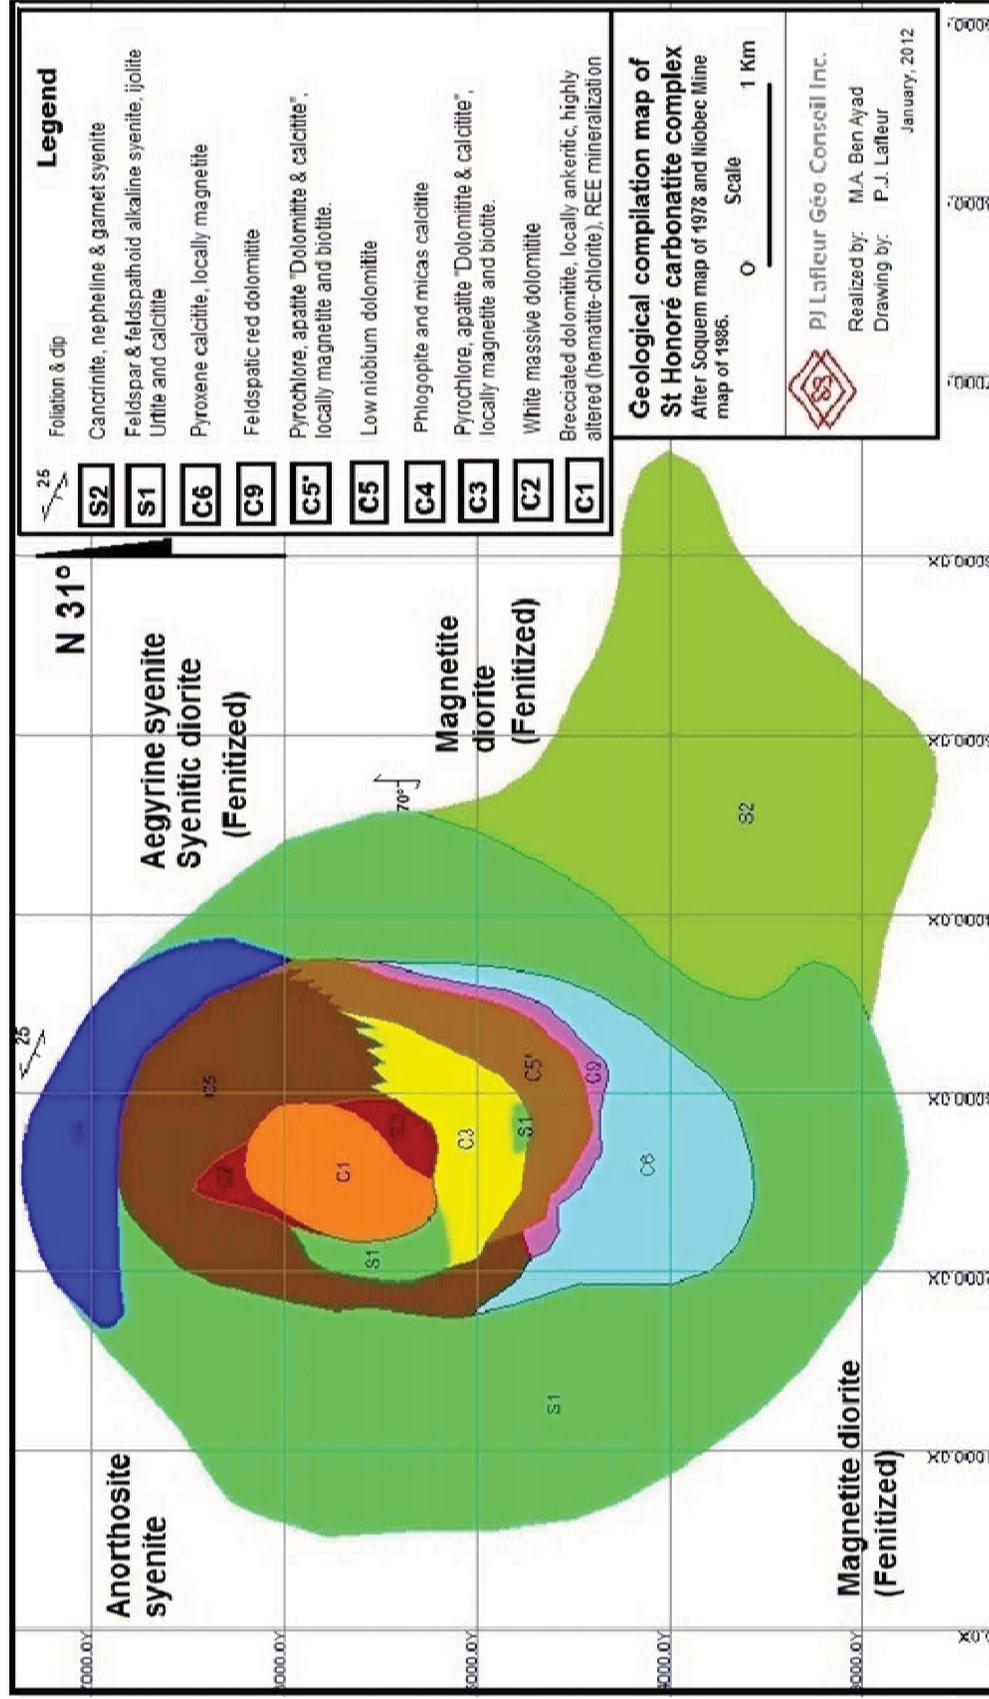

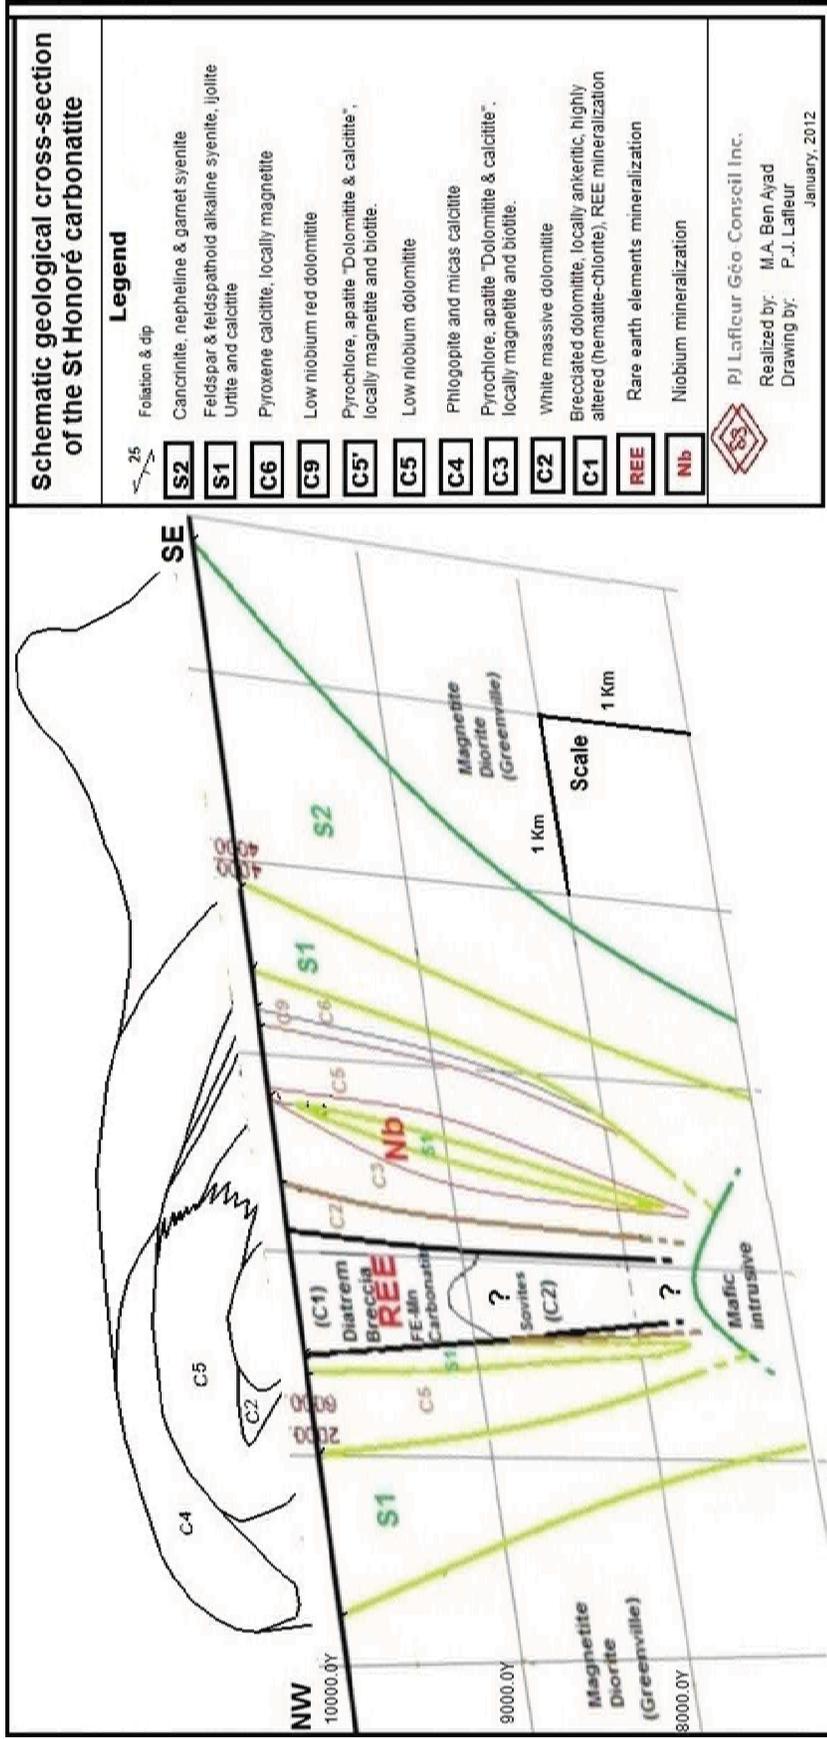

Figure 6: Geological schematic block diagram of the St-Honoré Carbonatite Complex (NW-SE cross section)

Beside these ring-dykes and cone-sheets, numerous calcitic and dolomitic dykes, cogenetic to the dolomitite and calcitite cone-sheets, have been cross-cut by Soquem drill holes (Fortin, 1977).

Regarding the dip of these different ring-dykes and cones-sheets constituting this carbonatite complex, besides the shallow exploration drill holes data of Soquem interpreted with a 70° dipping structures (Vallée and al., 1969), mine drill holes data (surface and underground), show to a depth of 800m, a sub-vertical to 70° dipping to the north of the Mine carbonatite structures (C5 and C3).

Considering the concentric structure of this carbonatite complex, a conical geometry with a strong dip of the different units toward the center of the cones remains the more probable scheme for this carbonatite complex.

A northwest-southeast schematic geological cross section has been established, to better visualize and understand the spatial internal organization of the St-Honoré carbonatite complex (Figure 6).

9.2.1.3 The Carbonatite complex Zoning

Following the petro-geochemical study of the carbonatite complex (Fortin, 1977), zoning seems to manifest itself between the different facies units of the carbonatite regarding their geochemical composition and their chronology:

- The carbonatite complex has a reniform shape consisting of a central portion of carbonatic rocks enclosed in an alkaline syenite;
- The age of the different units of the syenite show a chronologic evolution in the following magmatic suite from "Ijolite-Urtite-Foidite (to) syenite-Feldspathoidic syenite (to) Alkali syenite-Lamprophyre-Carbonatite";
- The age of the different units of carbonates decreasing progressively inwards from alkali syenite, calcitite through dolomitite to ferro-carbonatite;
- The carbonatite comprises concentric lens which evolved from calcitite through dolomitite, to a brecciated core of ferrocarnatite;
- The carbonatite shows an outward inward carbonate evolution expressed mineralogically by the suite "calcite- dolomite- ankerite-siderite",

In spite of the similarities with other carbonatite complexes, (1) such as the presence of a carbonatite core bordered by a syenite in Oka, (2) zonality between calcitite and dolomitite as in Firesand carbonatite (Superior province, Ontario), the St-Honoré carbonatite complex is different by the absence of ultramafic rocks as in Oka (Fortin, 1977).

9.2.1.4 REE zone geology

9.2.1.4.1 First geology model (Denommé, 1985)

The REE Zone forms the core of the complex (C1), and has an oval shape, elongated towards the northeast with an area of 650 000 m². This zone is differentiated from the Main Zone (Niobec mine area: C3 and C5) by its extensive brecciation, the presence of ankerite and high REE content.

Immediately surrounding it (C1), Dénoimé (1985) describes a zone of extensively altered dolomitite, which is brecciated but does not host REE minerals. After the 2011 and 2012 works, this surrounding zone is now called the Transition zone where a variable proportion of mineralized C1 brecciated the adjacent carbonatite facies (C2 and C5) or syenite (S1). REE mineral are observed and the proportion of C1 generally increased toward the core zone. The variable proportion of mineralization in the transition zone created a low grading halo (0.5-1% TREO) around the high grading core (>1% TREO). The economic potential of the Transition zone depend on different factors but must be seriously evaluated.

Three main types of breccia have been distinguished by different authors in the REE Zone:

- Reddish breccia corresponding to a rich hematitic breccia;
- Greenish breccia corresponding to a chlorite rich breccia;
- White to beige breccia, which looks like unaltered breccia.

A more recent petrographic, mineralogical and geochemical study (Fournier, 1993) allows a better description and understanding of the REE Zone.

9.2.1.4.2 Petrographic and mineralogical highlights of the REE zone

At a macroscopic scale and below the paleo-meteorite alteration zone (about 60m below surface), the brecciated dolomitite (C1 facies) is greenish to reddish colored, respectively made by chlorite or hematite present in the matrix, and varies from clast to matrix-supported. The clasts are rounded to sub-angular and composed of dolomite, ferroan-dolomite, ankerite and siderite. They range from 0.25 cm to a few centimetres in diameter but the described thin "horizon" of carbonatite left intact are probably larger clasts of pluri-metres scale. Locally, K feldspar clasts have been signaled in these brecciated facies, particularly in the chloritic breccia (Gauthier, 1979).

Dolomite, ankerite, siderite, calcite, feldspar K, hematite, chlorite, REE minerals (REE fluorocarbonates and monazite), sulphides (pyrite, sphalerite) are the chief minerals in the breccia and occur in varying proportions (Gauthier, 1978; Fournier 1993).

The unbrecciated horizons are whitish to buff colored, and are usually devoid of most of the accessory minerals (minor phlogopite, magnetite and apatite).

Late, 1-3 mm wide, partially to completely filled veins, containing euhedral calcite, barite and fluorite cut across the brecciated and also across the unbrecciated dolomitite (Fortin, 1977; Fournier, 1993).

The uppermost 60 m of the REE Zone were heavily weathered to an orange or red color as a result of exposure of the carbonatite to the atmosphere prior to deposition of the Trenton limestone (Figure 7). At depth, red staining of carbonates is a more local phenomenon, and the characteristics of the breccia are easier to recognize (Dénommmé, 1985; Fournier, 1993).

At the microscopic scale (Fournier, 1993), dolomitite clasts range from an Mg-rich variety to a more iron-rich variety containing significant manganese. They make up a solid solution between dolomitite and ankerite, but some crystals of magnesian siderite are also found.

The carbonates cement of the breccia varies from ferroan dolomite to ankerite but is poorer in Ca than the associated clasts.

The chlorite is brownish colored, iron-rich and locally comprises up to 20% of the rock by volume in interstices between carbonates grains. This contrasts with the Mg-rich, greenish variety, which replaced phlogopite in the Niobium Zone (Fournier, 1993).

The apatite, which classifies as fluorapatite, has higher fluorine content and a more stoichiometric phosphorous content in the REE zone than in the Niobium zone. However, the REE content of apatite from the two zones does not differ significantly.

The principal REE minerals are fluorocarbonates and take the form of needles in radiating bundles or in parallel growth and measure a few microns in diameter and up to 20 micron in length. REE fluorocarbonates minerals are concentrated mainly in the breccia matrix where they are associated with either chlorite, hematite, dolomite or organic matter.

The monazite [(REE,Th) PO₄] occurs as irregular, micron size grains spatially associated with parisite but enclosed in the bastnaesite; and the thorite (ThSiO₄) as micron size, opaque, grains set in either chlorite or organic matter.

The oxide minerals in the REE zone, the hematite, is found either as discrete fine (<0.05 cm) metallic grains (specularite) or as a reddish coating on other minerals. The main sulfide mineral, the pyrite, occurs as euhedral grains (0.02 to 0.05 cm) or stringers of sub- to anhedral crystals in breccia zones.

Euhedral crystals are commonly replaced or surrounded by hematite.

Pyrrhotite and chalcopyrite have also been observed as inclusions within pyrite. The subhedral sphalerite is also encountered with the pyrite in the stringer.

Anthraxolite, a bituminous hydrocarbon of the asphaltite group, is commonly present in the upper, superficially altered portion of the carbonatite. The occurrence of anthraxolite is not restricted to the REE zone as originally believed, but does appear to be confined to the superficial altered portion of the carbonatite.

Phlogopite in the REE zone is a minor phase which occurs mainly as fine grained in the breccia, surrounded par a chlorite halo.

Rare ilmenorutile, a niobilum-bearing phase, form small euhedral crystals (<0.25 mm) in the breccia.

The occurrence of strontianite, celestite and rhodocrosite has been reported by Gauthier (1979).

Euhedral barite, fluorite and calcite are the late minerals phase and filled the veins and vugs.

9.2.1.4.3 Origin of the core breccia:

From the conical geometry of the REE zone, two mechanisms have been proposed to explain its formation:

- Contraction cracking due to cooling (Gauthier, 1979),
- Hydro-brecciation from igneous activity (Fournier, 1993).

Gauthier proposed that the REE zone breccias had formed by contraction during cooling, following the buildup of the multiples cones sheets corresponding to the different breccia facies defined in the deuteric alteration zone. His model has been abandoned by different author following the results of the deeper drill holes realized since 1985. Regarding the brecciation, it seems unlikely that such a small area of the complex would have been affected by this process, and even less likely that the latter could have caused such intense brecciation (Fournier, 1993).

On the other hand, Fournier in his model of hydro-brecciation considered the brecciation analogous to resurgent boiling in the granitic systems and the residual melt could have saturated with an aqueous phase due to insufficient crystallization of hydrous minerals. Separation of this fluid from the magma could have caused a sharp buildup in pressure, resulting in overpressures that could have exceeded the strength of the carbonatite. If this was the case, hydrofracturing would have initiated, and this could ultimately have led to the production of a breccia pipe by the escaping fluid.

Support for this interpretation is provided by the high proportion of secondary vapor inclusions (Fournier, 1993) in the primary dolomite and ankerite (not reported in Heinritz and al, 1989).

9.2.1.4.4 Conclusion of the petro-mineralogical study of REE Zone

Petrographic and mineralogical highlights are based over historical works led by Fortin (1977), Gauthier (1979) and Fournier (1993). Additional drilling of the REE Zone has been realized recently (2011 and 2012) by IAMGOLD-Niobec. Thus 61 drill holes, totaling 37,649 m of new data, confirmed and update, particularly at depth, the previous observations. In 2012, IAMGOLD and UQAC (Université du Québec à Chicoutimi) collaborated in a new petrographic, mineralogical and geochemical study. A master project, realised by Alexandre Neron, Geo. Stag. and supervised by Paul Bédard, Ing. Ph.D. will focus on the REE zone and the new drilling datas.

The observation, at a macroscopic scale, of some of the core of these recent drill holes confirm all the macroscopic petrographic data mentioned above with additional and complementary information, thus:

- These breccia correspond to hydrothermal breccia related to igneous activity, attested by the multiple hydraulic breccia structures;
- Presence of multiple breccia phases (brecciation of breccia);
- The REE zone is constituted by mainly ferrodolomitite breccia with the presence locally of, a mineralized or not, calcitite breccia facies;
- The breccia zone shows the existence of numerous clasts of syenite highly altered corresponding probably to xenoliths;
- Presence of at least two mineralized phases expressed by the presence of lanthanides in the carbonates elements of the breccia (impregnation) and mainly in the matrix of this breccia;
- Presence of at least a mineralized alteration front affecting all the core breccia (dolomitic and calcitic) testified by the existence of small barren zones of the different brecciated facies or small patches of different sizes in the mineralized zones.

These observations confirm the existence of multiple stages of igneous activity and a metasomatic replacement characteristic of the carbonatite complexes.

Based on petrographic observations, the paragenesis of REE Zone can be subdivided into four stages (Fournier, 1993):

- The first consisted of the crystallization of a dolomite low in Nb and REE (C2),
- This was followed by brecciation (C1) and deposition of synchisite and possibly parisite, monazite and thorite. Ankerite, ferroan dolomite, hematite and chlorite were also introduced in this stage,
- The next stage consisted of the formation of veinlets of barite, fluorite and calcite,
- The last event was the meteoric alteration which caused hematization.

This model is in accordance with the chronology of the whole carbonatite complex buildup, advanced by Fortin in 1977:

“The setting-up chronology could be, considering the petrographic observations, the geochemical study and carbonates common setting up order:

1. *Sovites (Calcitites) of the south (C6) and the north (C4) of the carbonatite complex,*
2. *Rauhaugites (Dolomitite) of the economic zones (C9, C5 and C3) and the low Niobium and REE dolomitite (C5),*
3. *Dolomitite of the central zone (C2 and C1 non brecciated),*
4. *REE carbonates like cement of the low REE rauhaugites cavities,*
5. *Sequent veinlets with calcite, quartz, barite and fluorite”*

Apatite-phlogopite geothermometre yielded a magmatic temperatures between 1150 and 800°C for the SHCC. The REE zone temperatures range between 380 and 346°C and reflected the subsolidus conditions. An independent chlorite geothermometre yielded similar temperatures (364 to 321°C) for the REE zone breccia cement (Fournier, 1993).

A satisfactory model for the whole carbonatite is proposed by Fournier (1993) within the framework of his master memory and is resumed by the author as follows:

“REE concentration in the magma was initially buffered by the crystallization of pyrochlore and apatite (Niobium zone), and was subsequently allowed to build up when these phases stopped crystallizing in the most evolved ferrocarnatite. Saturation of this magma with water, late in its crystallization history, led to the separation of an acidic fluid into which the REE were strongly partitioned in fluorocomplexes. Analogous to boiling in granitic systems, this fluid brecciated the core of the carbonatite, and effervesced, causing an abrupt drop temperature due to adiabatic expansion, which combined with the pH buffering of the fluid by the dolomite, caused the precipitation of the REE as fluorocarbonate minerals”.

It's important to notice that these REE correspond essentially to LREE (Light REE) which is characteristic of the REE deposit associated to carbonatite, like REE minerals develop in the late stages of carbonatite emplacement (Kupta and Krishnamurthy, 2005).

Item 10. REE DEPOSIT TYPES

The following is a summary of different papers regarding REE deposits and particularly a recent compilation of the British Geological Survey (BGS) published in November 2011.

10.1 REE Major deposit classes

REE mineral deposits are known (Walters A. & co., BGS) to occur in a broad range of igneous, sedimentary and metamorphic rocks. The concentration and distribution of REE in mineral deposits is influenced by rock forming and hydrothermal processes including enrichment in magmatic or hydrothermal fluids, separation into mineral phases and precipitation, and subsequent redistribution and concentration through weathering and other surface processes. Environments in which REE are enriched can be broadly divided into two categories:

- Primary deposits associated with igneous and hydrothermal processes, divided into two categories, one associated with carbonatites and related igneous rocks and the other with peralkaline igneous rocks (Samson and Wood, 2004).
- Secondary deposits concentrated by sedimentary processes and weathering (supergene process).

Within these two groups REE deposits can be further subdivided depending on their genetic association, mineralogy and form of occurrence.

The worldwide most advanced REE project, including IAMGOLD-Niobec REE project, are listed below and could be consulted on the Technology Metals Research website (<http://www.techmetalsresearch.com/metrics-indices/tmr-advanced-rare-earth-projects-index/>). The Index, last updated on December 29, 2012, currently consists of 49 rare-earth mineral resources, associated with 45 advanced rare-earth projects, 43 different companies and located in 31 different regions within 14 different countries.

10.2 Carbonatite-associated deposits

Carbonatites are igneous rocks that contain more than 50 per cent carbonate minerals (IUGS). They are thought to originate from carbon dioxide-rich and silica-poor magmas from the upper mantle. Carbonatites are frequently associated with alkaline igneous provinces and generally occur in stable cratonic regions, commonly in association with areas of major faulting particularly large-scale rift structures.

More than 500 carbonatites occurrences are documented worldwide, with the main concentrations in the East African Rift zones, eastern Canada, northern Scandinavia, the Kola Peninsula in Russia and southern Brazil (Woolley and Kjarsgaard, 2008). Carbonatites take a variety of forms including intrusions within alkali complexes, isolated dykes and sills, small plugs or irregular masses that may not be associated with other alkaline rocks. Pipe-like bodies, which are a common form, may be up to 3-4 km in diameter (Birkett and Simandl, 1999).

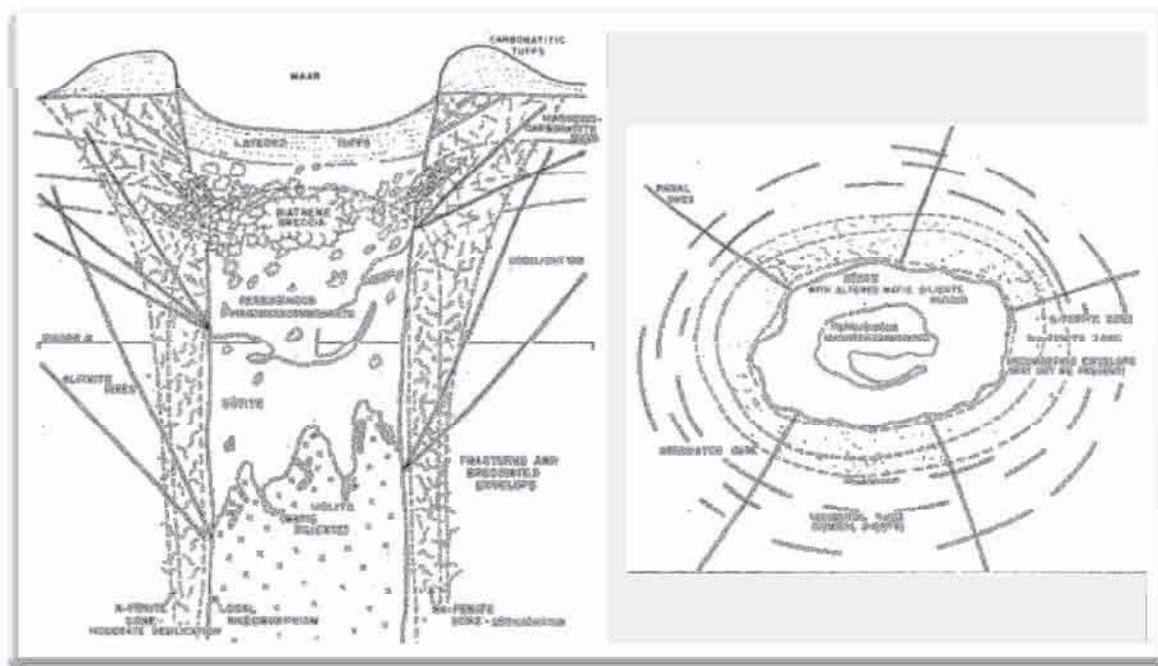

Intrusive carbonatites (Figure 7) are commonly surrounded by a zone of metasomatically altered rock, enriched in sodium and/ or potassium. These desilicified zones, known as fenite, develop as a result of reaction with Na-K-rich fluids produced from the carbonatite intrusion.

The REE are largely hosted by rock-forming minerals where they substitute for major ions. Higher concentrations of REE are required to form their own minerals (Miller, 1986). Around 200 minerals are known to contain REE, although a relatively small number are or may become commercially significant.

The REE in carbonatites are almost entirely LREE which occur in minerals such as bastnaesite, allanite, apatite and monazite (Gupta and Krishnamurthy, 2005). REE do not occur naturally as metallic elements, they occur in a wide range of mineral types including halides, carbonates, oxides and phosphates.

The vast majority of resources are associated with just three minerals, bastnaesite, monazite and xenotime. In some REE minerals, the LREE are particularly enriched relative to the HREE, which in others the opposite is the case. Bastnaesite and monazite are the primary source of the LREE, mainly Ce, La and Nd. Monazite has a different balance as it contains less La and more Nd and HREE. It is also significant to note that monazite contains the thorium, a radioactive element.

Figure 7: Schematic section and plan view of a carbonatite complex (SIDEX.ca)

Schematic section and plan view (mid-level) of a carbonatite complex, showing cylindrical shape of intrusion that evolves upwards into a diatreme breccia and layered tuffs. Late dikes (bold lines) display a radial or concentric pattern. The intrusion consists of three phases: sövite (calcite-rich carbonatite), iron-rich magnesians carbonatite, and ijolite (nepheline-pyroxene rock). The host rocks are fenitized (alkaline metasomatism) and desilicified.

Item 11. MINERALIZATION

11.1 REE mineralization general description

The principal REE minerals observed in by different authors the brecciated facies of the REE Zone (Vallée & Dubuc, 1970; Nickel & Pinard, 1970; Gauthier, 1979), correspond first to basnaesite and monazite. They are often accompanied with minor amount of pyrrhotite, chalcopyrite, huttonite (ThSiO_4) and molybdenite.

The following information come from a more detailed metallographic study describing the REE minerals (Fournier, 1993). The REE minerals, fluorocarbonates, are needles shaped and formed radiating bundles or growth in parallel. They typically measured a few microns in diametre and up to 20 micron in length. These REE minerals are from a solid solution produced between the Bastnaesite [$\text{REE}(\text{CO}_3)$] and Vaterite (CaCO_3) end-member, including; parasite [$(\text{CaREE}_2\text{F}_2(\text{CO}_3))$] and synchysite [$\text{Ca}_2\text{REE}(\text{CO}_3)_2$] the intermediate members. The REE fluorocarbonates are consisted of an early Ca-rich phase, probably synchysite and possibly parasite, enclosed by a later Ca-poor phase, probably bastnaesite. Additional phase of intermediate compositions, as parasite, may be possible (SEM imaging and qualitative EDS from Fournier, 1993).

Fluorocarbonates minerals are concentrated mainly in the breccia matrix where they are associated with: chlorite, hematite, dolomite or organic matter.

Monazite [$(\text{REE,Th})\text{PO}_4$] and thorite (ThSiO_4) are the second important host of REE after the fluorocarbonates. Monazite occurs, as irregular shaped grains of micron size, spatially associated with parasite but enclosed in the bastnaesite. The thorite occurs as micron scale and opaque grain set in either chlorite or organic matter.

Besides the REE minerals (REE fluorocarbonates and monazite), an inventory of different minerals has been established by different authors:

Carbonates:	Dolomite, calcite, ankerite, siderite.
Fluorocarbonates:	Bastnaesite, synchysite, parasite.
Silicates:	Chlorite and phlogopite, feldspaths (K), quartz, vermiculite (?), zircon, amphiboles, pyroxenes and epidote.
Phosphates:	Monazite and rare apatite.
Oxydes:	Magnetite, hematite, ilmenite, rutile, goethite, pyrolusite and pyrochlore.
Sulfures:	Pyrite, pyrrhotite, sphalerite, chalcopyrite, molybdenite (?)
Others:	Baryte, fluorite, antraxolite, and numerous non identified minerals.

Based on petrographic and metallographic observations, a paragenesis succession (Table. 3) has been established (Fournier, 1993).

Table 4: Paragenetic sequence for the REE Zone minerals (Fournier, 1993).

11.2 REE mineralized envelope

Considering the REE Zone drill holes compilation map (Figure 19), few drill holes were realized between 1967 and 1985 (totaling 3,902 m). The geometry of the mineralized envelope, drawn as the geological core zone (C1), was principally based over the magnetic interpretation (Vallée & Dubuc, 1970).

In 2011 and 2012, 37,370 metres were drilled by IAMGOLD-Niobec. Even if the REE zone limits were better defined by the new drilling program, the mineralized envelope roughly respected the first geological interpretation. The REE deposit has a spherical shape with a North-East elongation on plan view and covers an area at the sub-surface of about 1 km² (Figure 5). The conical shape initially interpreted has changed to a more cylinder geometry down to 400m depth and was confirmed by the 100x100m drilling mesh. The 400m to 700m vertical axis is covered by a 100x200m drilling mesh. Based on this definition, the mineralized cylinder may be interpreted down to 700m with a high level of confidence. The deepest holes tested the mineralization continuity down to 1200m. Even if the lateral extensions are well confined, the core zone is still open at depth.

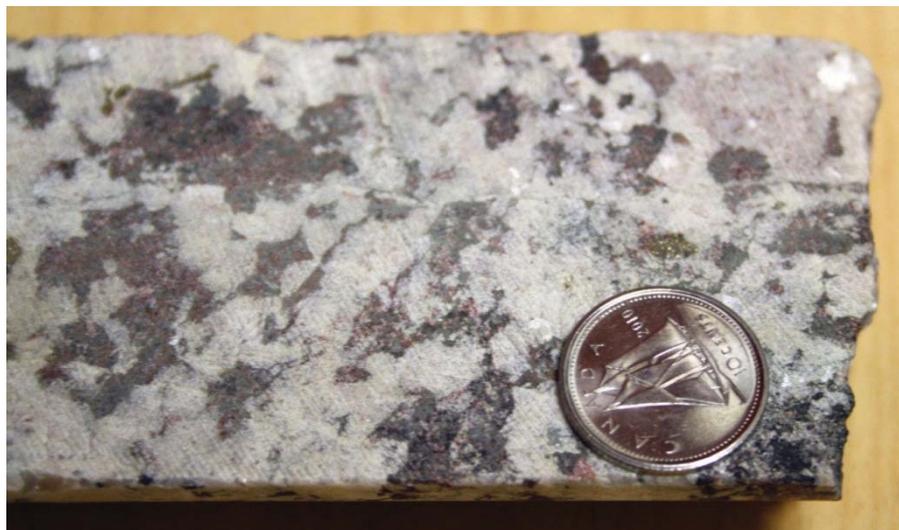

The distribution of the overall TREO values (Total REE oxides) varied from 0.01% to 12.34%. The overall average value is 1.75 % TREO. The interpreted high grade, >2% TREO, mineralized envelope (Figure 8) is associated to the brecciated and massive facies of the ferrocarnatite.

Figure 8: High grade mineralized envelope (>2% TREO).

The massive carbonatite is principally composed of coarse grained iron-dolomite $[\text{Ca}(\text{Mg,Fe,Mn})(\text{CO}_3)_2]$, sometime ankérite $[\text{CaFe}(\text{CO}_3)_2]$, pyrite $[\text{FeS}]$, barite $[\text{BaSO}_4]$ and red/purple colored REE-rich clusters (Figure 9). The calcite $[\text{CaCO}_3]$ is partially or completely replaced by siderite $[\text{FeCO}_3]$ associated with yellow colored carbonates. The massive C1 facies is cut by late calcite injections, apatite/halite injections and biotite injections associated with fault plans. The open faults have idiomorphic crystals of barite, pyrite, fluorite, halite and strontianite.

Figure 9: Mineralized massive carbonatite (C1L).

The red/purple clusters composition was defined with a portable XRF and with a cartographical technic by u-XRF (UQAC University). They are composed of REE minerals, barite [BaSO₄], calcite [CaCO₃], quartz [SiO₂], hematite [Fe₂O₃] and halite [NaCl] (Figure 10). The proportion of minerals in the clusters are really variable from each to other but more homogeneous over the ore deposit. Around 400m, a differentiation of clusters composition can be identified. In the firsts hundred metres, hematite, calcite and silicate are associated with REE minerals. At depth, past 400m, the halite and the barite appeared in the clusters composition with depletion of calcite and silica. REE minerals proportion, 20% of the cluster, is stable.

The REE minerals composing the clusters are defined by scanning electron microscope (SEM). Small (10-20 microns) needles of bastnaesite [REE(CO₃)F] (Figure 11) and monazite [REEPO₄] are identified (Néron, A. communication, 2013). The exact composition of the bastnaesite should be investigated (by microprobe) to know the Ca proportion in bastnaesite. The bastnaesite is the major REE minerals in the clusters but, at the depth of 900m, the monazite proportion increased.

The massive carbonatite (C1) is brecciated by a fluid similar as the clusters composition and created the breccia facie (BRC1) (Figure 12). The mix of hematite, silice, chlorite/biotite, halite, REE-mineral, pyrite, calcite and/or calcite composed the breccia. The clasts seem from the massive facies and sometimes, but rarely, of syenitic rock. The breccia intensity is variable. Texture changed from 60% matrix supported with small and round shaped clasts to clasts supported breccia with angular fragments. When the magmatic degree of deformation is low, the C1 clasts can be easily re-built. In general, a transition is observed between the low intensity breccia and the massive C1 facies. When the deformation degree is higher, the breccia intersects the others units, even other breccia facies, with a sharp contact.

Figure 10: Variation of the mineralized clusters composition with depth (Hole# 2012-REE-052)

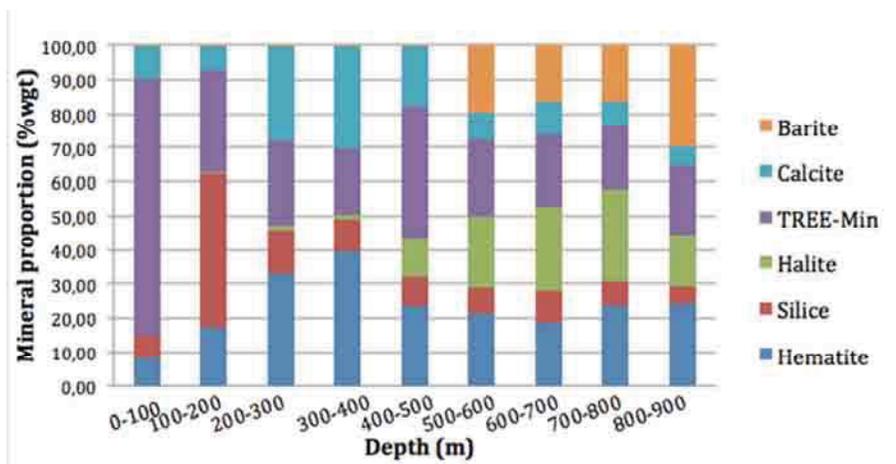

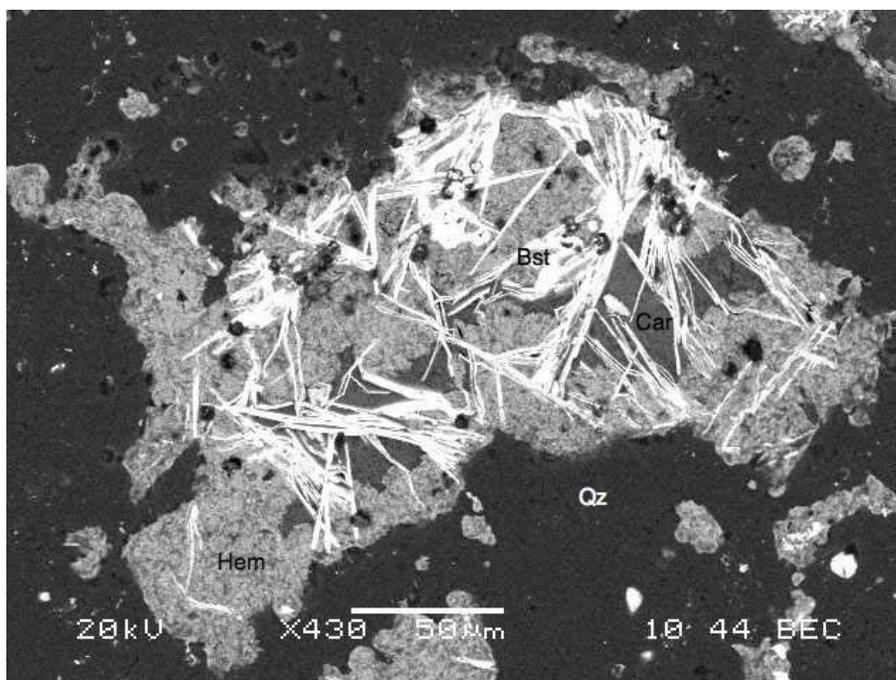

Figure 11: Mineralized cluster composition. (Hole# 2012-REE-033; Bst = bastnaesite; Qz = quartz; Car = carbonate; Hem = hematite)

Like the clusters in the massive unit, the matrix composition varied at depth. The silicate and calcite phases are observed before the 400m limit and the halite and barite phases are found below this limit. The REE minerals are disseminated in the matrix and represent 0.2 to 3 wgt% of the rock. Red to purple agglomerations of REE minerals are visible in the high intensity breccia.

Figure 12: Mineralized carbonatite breccia facies (BRC1L).

The REE mineralisation presented no relationship with the different facies of the core REE zone. Several analyses cumulate during the 2011 and 2012 drilling program show the homogeneity of the mineralization inside the ferrocarnatite (C1) envelope. The low grade zone, are localized in the periphery and correspond to the transition zone. In this zone, the REE mineralisation is still in the C1 facies. The amount of mineralized C1 intruding the adjacent lithology (C2, C3, C5 and S1) decreased going outward from the center.

Item 12. EXPLORATION

Exploration and resource development drilling is concentrated within the carbonatite complex where the economic concentration of niobium is known. Since 1985, no exploration works for REE have been done until the drilling campaign started by IAMGOLD in 2011 and continues through 2012.

12.1 Scoping Study

Exploration program focused on the REE zone. The drilling program has continuously progressed. The delimitation program, initiated in 2011, ended in May 4th 2012 by the completion of the hole 2012-REE-039. A total of 10 holes were added in 2012 to the initial 28 holes performed in 2011, including two deep holes (2012-REE-033 and 2012-REE-034), for a total of 22, 072 linear metres.

12.2 Prefeasibility study

Since May 5th, 10 other holes have been added to define the REE zone over a 100 x 100 metres drilling grid through the depth of 400 metres and a 100x200 metres drilling grid through the depth of 700 metres. The additional 15, 779 linear metres drilled between May to

August are part of the pre-feasibility program. This included the hole from 2012-REE-040 to 2012-REE-061.

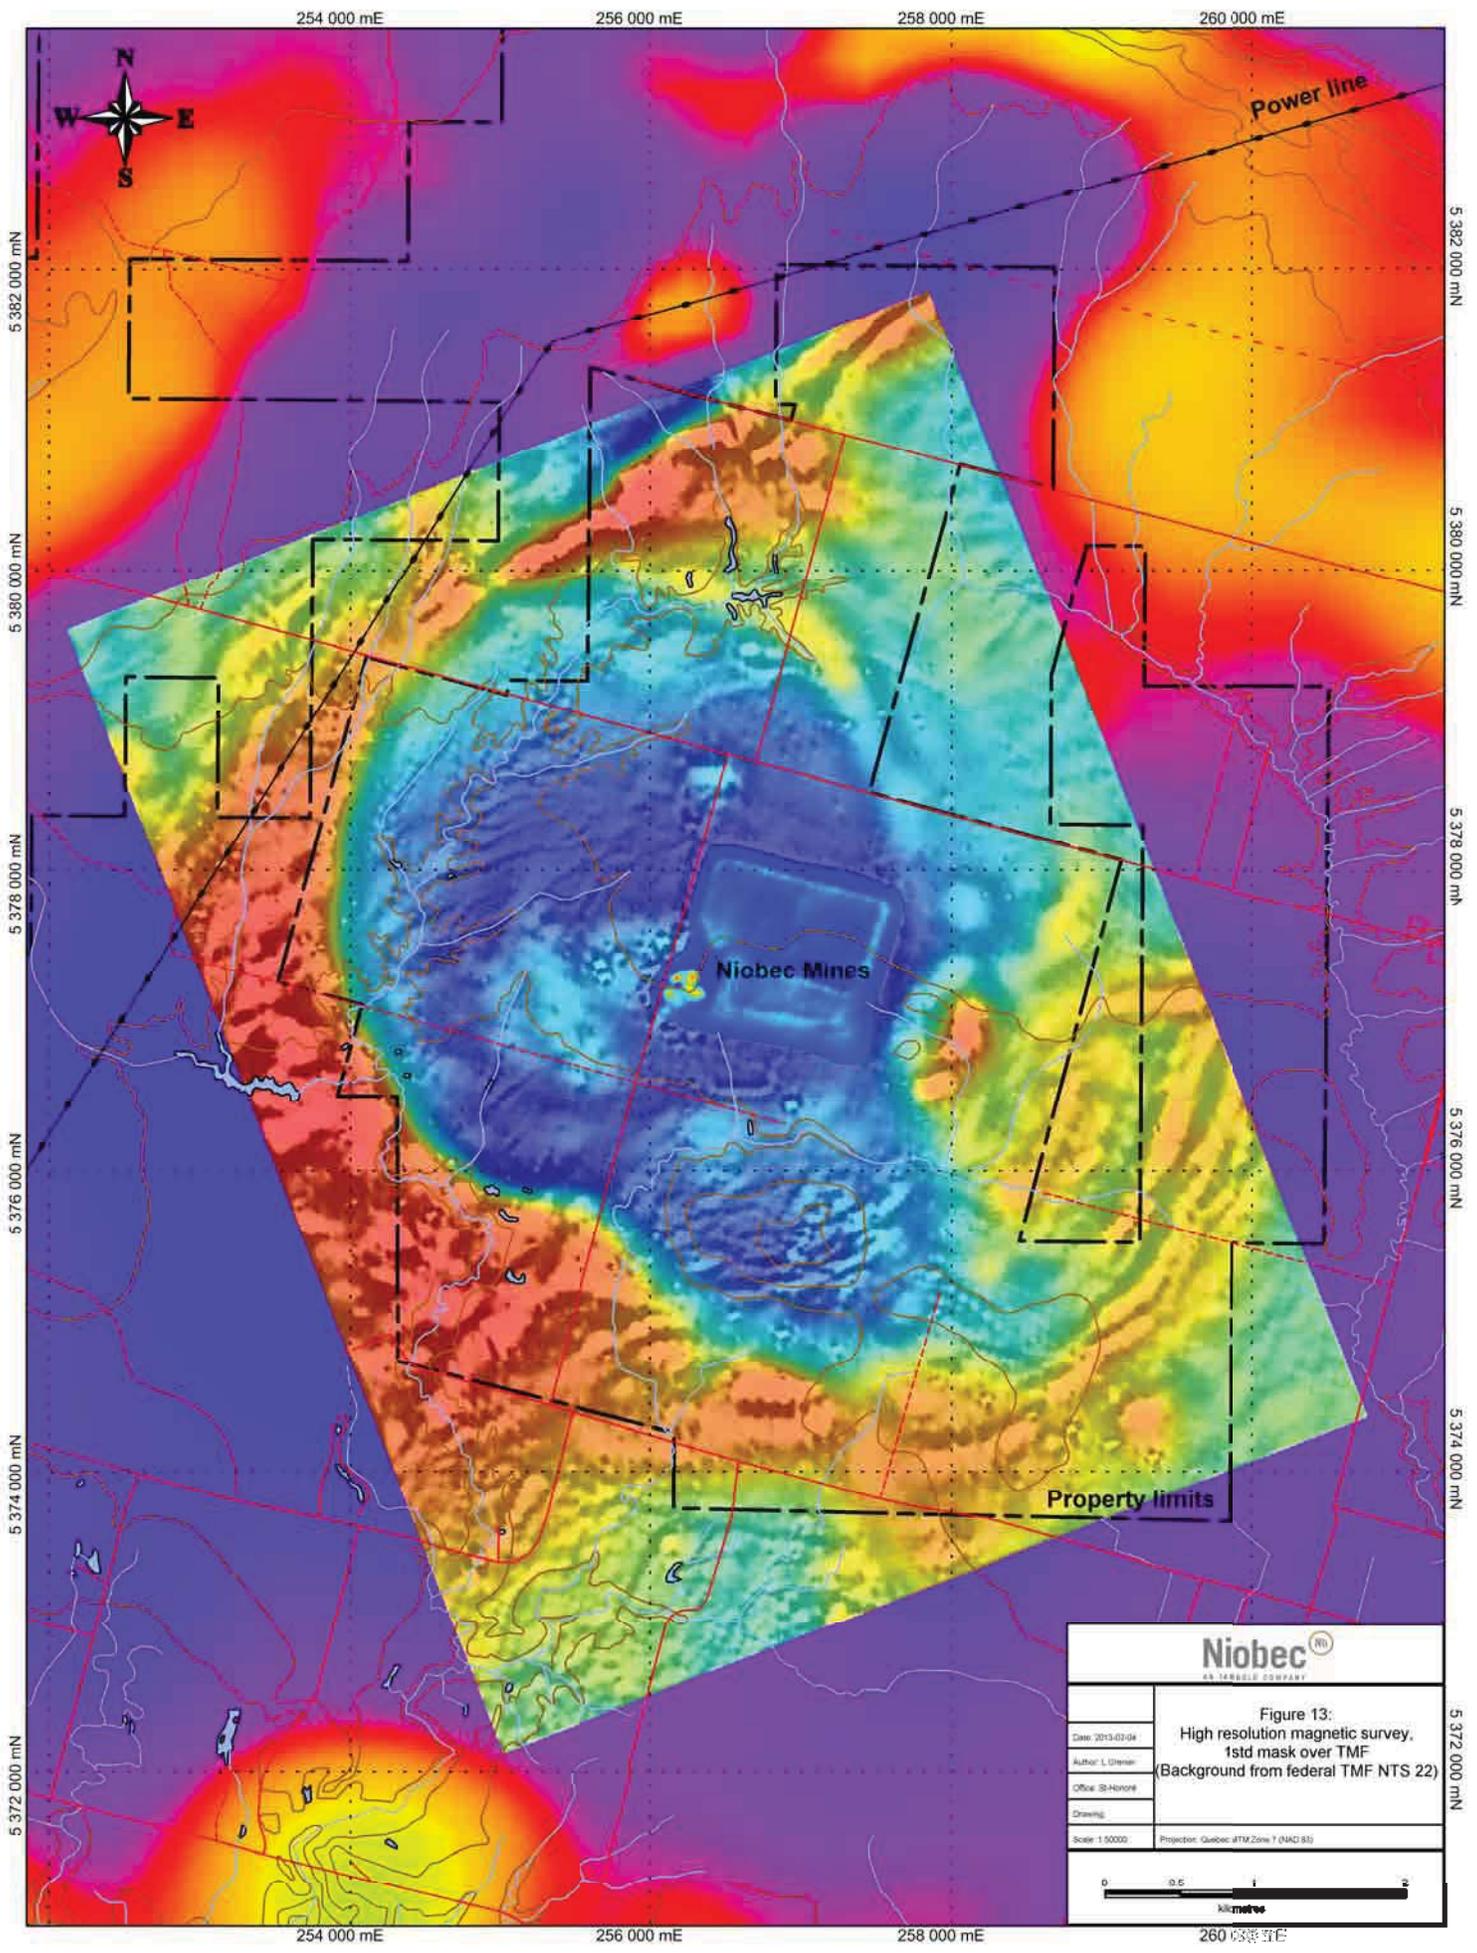

Parallel to the surface activities, underground development started in October 2012. An exploration drift was driven through the core of the REE zone. The drift started from the mine level 1150, about 300m below surface, and followed the section 2600E of the exploration grid (Figure 14). Driven from the south, the transitional zone (between Niobec ore zone and REE zone) was crossed and an increasing amount of the REE mineralized carbonatite (C1L) was noted. This unit showed a clear brecciating relationship with the adjacent massive carbonatite (C2). The association between the C2 and the C1 was confirmed. The drift layout was planning to stay in the mineralized carbonatite breccia facies (BRC1L). Before the development completion, some representative mineralized material was stocked and characterized underground. Preliminary assays returned an average value of 2.0% TREO for about 3,500 tonnes bulk sample. This material is reserved for additional metallurgical testworks.

12.3 Other field work

The heliborne high resolution mag survey over the Niobec property was completed by EON geosciences Inc. during May 2012. The complete survey parameter can be consulted in the final report produced by the contractor (Appendix 3).

The carbonatite total magnetic field strongly contrast with the grenvillien hosting rock and the new airborne survey confirmed the main geometry of the complex (Figure 13). The high definition aspect outlines small variation inside the carbonatite magnetic signature. Facies variation or structural domain may create this variation. The sensibility of this magnetic survey method is affected by the Niobec mine activities. The anthropic distortion affected the nearby mine area and complicated the interpretation.

The final data has been treated by Mark Goldie, IAMGOLD chief geophysicist, and sent to Niobec geological team for validation and exploration duty. This new information, coupled with the surface diamond drilling will be used to update the Niobec geological map.

Item 13. DRILLING

13.1 Historical diamond drilling and statistics

The St-Honoré carbonatite complex is covered by a layer of Paleozoic sediment variable in thickness. Historically, the REE zone could be studied with one outcrop located in the North-East area of the core zone but the discovery showing was covered by a layer of overburden moved during the mine operation. Diamond drilling is the best and the only method of investigation used by IAMGOLD and the various site operators.

In 1967 the drilling program tested the new radiometric anomaly discovered. Few short hole confirmed the anomalous REEs concentration in the ferrocarnatite. In 1975, a preliminary definition of the core zone (C1) was completed. In 1985, Soquem completed three long hole to characterised and test the continuity at depth of the REEs zone. The compilation map, show the historical drill holes location (Figure 14).

After a latency period of 26 years, IAMGOLD decided to launch a large diamond drilling program stimulated by a favorable REEs economical context. In the last two years (2011 and 2012) 90% of the data on the REEs zone was collected.

Table 5: Historical diamond drilling on the REEs zone.

Company name	Year	Number of Drill Holes	Average LENGTH	Longest DH LENGTH	Total LENGTH (metres)	% of Total LENGTH
SOQUEM	1968	5	141	226	706	1.7%

13.2 Drilling realized by IAMGOLD

Drilling was performed between March 6, 2011 and October 9, 2012 over the Niobec property and specifically over the REEs zone. The first resource estimation (Lafleur, P.J. and al., 2012) was calculate with the data of the surface holes 2011-REE-001 to 2011-REE-028, and the underground hole S-3607. The program continued in 2012 with the realization of the holes 2012-REE-029 to 2012-REE-061. The 33 new holes, for a total of 23, 851 metres, were drilled under the supervision of Niobec geological team and are the object of this present report.

The objectives were to define the geological model, upgrade the resource definition for a new resource calculation and test the REE mineralization continuity at depth. The deeper holes

demonstrate the uninterrupted extension of the REE zone at depth, although the resource estimate reported only to 700 metres below surface.

13.3 Diamond drill hole summaries

The diamond drill holes have been localised by the Niobec mine surveyor team. The data is summaries in Quebec MTM83, zone 7, system (Table 6 and Figure 15-16) but an exploration grid coordinate system was daily used.

A summary of each diamond drill hole realized in 2012 is available below in the 13.5 section.

Table 6: Drill holes summaries, 2011 niobium exploration program.

HOLE-#	Explo grid (m)					Quebec MTM83, Zone 7 (m)			Title #	LENGTH
	Easting	Northing	Altitude	Az (°)	Dip (°)	Easting	Northing	Altitude		
2012-REE-029	2297.71	5497.56	9999.00	122.90	-49.50	255975.73	5378378.41	142.44	2713202	651.00

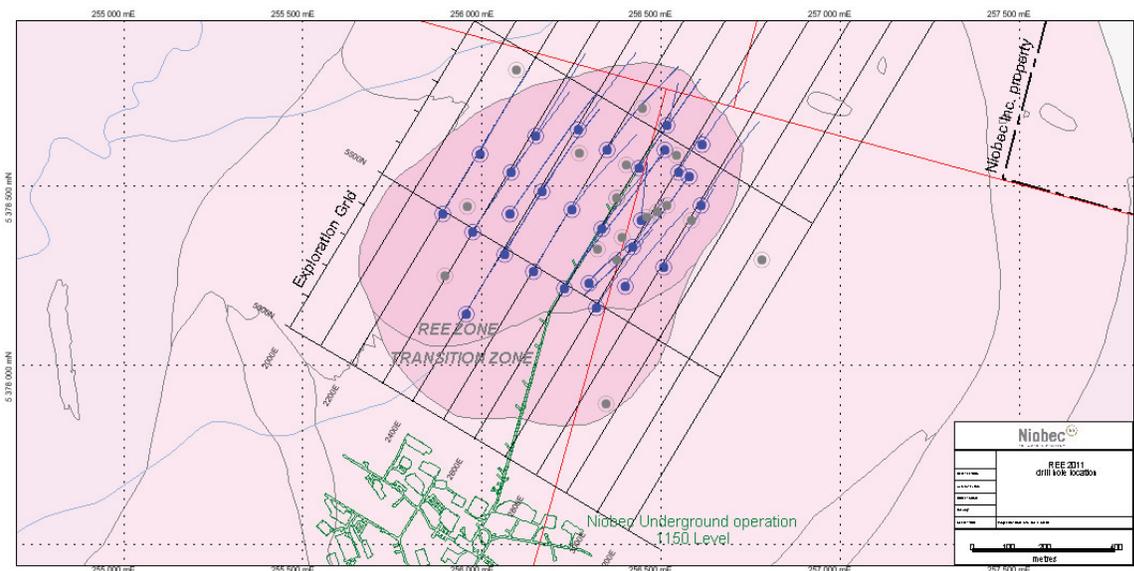

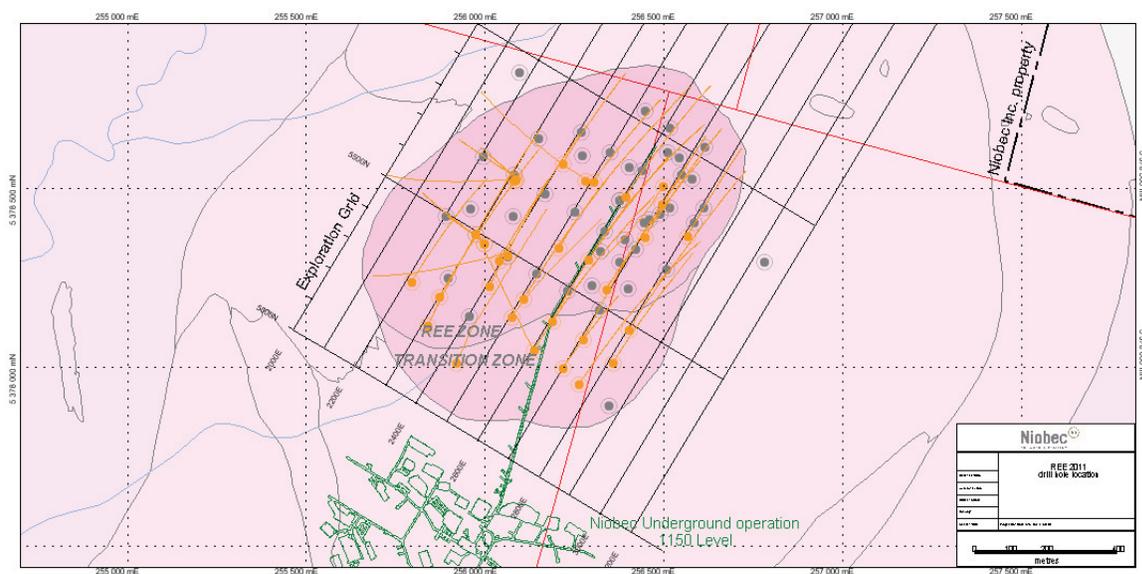

Figure 16: Drill holes locations, 2012 exploration program

13.4 Methodology

The Niobec exploration geologist, hired in March 2012, was responsible for all the steps necessary for the realization of a surface diamond drilling program. This included the drill set-up recognition, the permitting, the positioning and orientation of the drill, the supervision of drilling methods, the procedures application, the supervision of the health and safety rules, the environmental compliance and the restoration of the drill sites. Drill holes are planned by the Niobec mine geology team and approved by the IAMGOLD exploration general manager. The services of a contractor, IOS Services Géoscientifiques Inc. (“IOS”), were used to support the REE exploration program. IOS carried out core logging, sampling and shipping of the samples to the laboratory and worked in close collaboration with the Niobec mine geology team. .

The exploration geologist was also looking after the quality assurance and the quality control (QA/QC) for the REE Zone. That included the purchase of standardized material, the preparation of the blanks and compilation of results. Any samples for REE assays were performed at the Niobec mine laboratory, the entire drilling core samples were sent to SGS facilities, Lake Field Ontario after been logged, cut and bagged. See Item 16 for the details QA/QC procedures.

The whole drilling campaign has been realized by “Forage Boréal Inc.”, a drilling company located in Val d’Or, Abitibi, Québec. The exploration grid was generally used has reference. At the end of 2012, drilling mesh respected a 100 by 100 metres spacing. The main direction of drilling was N031° (N000° on the exploration grid) with a magnetic declination of 18° West, and a dip generally toward the North. Deviation was measured with a multishot survey

(Reflex EZ-shot) done after the end of each hole. No additional in-hole survey was performed in the existing drill holes from 2011.

In 2011, all the casing located in the farmed field has been pulled out after the holes were finished. From the hole 2012-REE-033, most of the casing were kept for further surveys (position, radiometry, geophysics, etc.) or other verifications can be made on selected holes.

Drilling was done in the field next to the mine office parking. The core shack is on the mine site, less than 1 kilometre from the drill rig. Core is retrieved from the drill rods using conventional wire line techniques. The core is removed from the core barrel by the drill contractor employee and carefully placed in standard NQ wooden core boxes. A wooden bloc with the depth written on it is put in the box at the end of each run (3 metres). Once filled, core boxes are closed and sealed. Boxes are removed from the drill site twice daily (at the end of each work shift) by the drilling contractor personnel and delivered to the core shack. Verification of all the boxes is proceeded (Inscription on the boxes, core length and tags, continuity between the boxes, etc.).

13.5 Drill hole description, 2012 REE exploration program

The location of each drill hole and an overview of the 100m x 100m drilling mesh realised during the 2012 exploration program can be consulted at Figure 19. The dilling sections figures covering the main area of the REE zone, is also available on appendix 1.

13.5.1 2012-REE-029

The 2012-REE-029 is situated in the center west area of the REE zone (MTME 255975.73: MTMN 5378378.41). It was drilled at 156° (true North) with a dip of -50°. The objectives were to intersect the South contact and delimit the REE zone. The overburden is 7.5 m thick. From 7.2 m to 44.5 m, the REE zone is covered by the Trenton limestone. The carbonatite begin with a strongly altered breccia (BRC1L) down to 141 m. The alteration is composed of hematite, chlorite and siderite and was formed by weathering of the carbonatite during the early Paleozoic. Pass the altered zone, the breccia zone, in a fresh facies, continues down to 230 m. From 230 m to 290.3 m, the breccia is cut by a massive calcitic and dolomitic carbonatite (C1L). From 290.3 m to 450 m, the breccia zone continued. The contact between the REE zone and the surrounding dolomitic carbonatite (C1) was traversed at 450 m.

The lanthanides mineralization is found in purple coloured, centimetre scale cluster in the massive facies. Size reduction is observed in the breccia facies but the proportion of lanthanide still the same. It is easier to estimate the lanthanide percentage in a coarser cluster facies. The assays returned a value of **1.704% TREO / 405.5 m** (from 44.5m) including **0.037% HREO / 405.5 m**.

13.5.2 2012-REE-030

The 2012-REE-030 is situated in the center area of the REE zone (MTME 256064.70: MTMN 5378319.66). It was drilled at 225° (true North) with a dip of -50°. The objectives were to intersect the South-West contact and delimit the REE zone. The overburden is 6 m

thick. From 6 m to 52.5 m, the Trenton limestone covered the carbonatite. At the contact between the limestone and the carbonatite, from 52.5 m to 55.5 m, a small interval of carbonatite conglomerate textured is observed. This transition unit was historically call regolith due to the in situ formation process. The strongly altered carbonatite breccia (hematite, chlorite and siderite) (BRC1L) continues to the depth of 151 m. The altered facies is followed by a fresh breccia facies (BRC1L) down to 229.5 m. From 229.5 m to 327 m, the breccia is layered with a massive dolomitic carbonatite facies (C1L). Few syenite enclaves are observed in this interval. From 327 m to 423.9 m, the breccia facies continue and the amount of syenite enclaves increased (C1S). The contact with the syenite is logged at 423.9 m depth.

The lanthanides had the same characteristics as previously described. The assays mark the contact with the REE bearing carbonatite and the not mineralized syenite. Enclave of carbonatite in the syenite returned punctual values in this interval. The mineralized carbonatite returned a value of **1.564% TREO / 277.5 m** (from 52.5m) including **0.035% HREO / 277.5 m**.

13.5.3 2012-REE-031

The 2012-REE-031 is situated in the North-West area of the REE zone (MTME 256083.37: MTMN 5378527.79) and was drilled at 235° (true North) with a dip of -50°. The objectives were to intersect the West contact and delimit the REE zone. The overburden is 8.2 m thick. From 8.2 m to 65.3 m, the Trenton limestone covered the carbonatite. The regolith, transition facies is observed from 65.30 m to 70 m. The strongly altered carbonatite (hematite, chlorite and siderite) begin with a calcitic breccia facies (BRC1L) down to 184.3 m. From 184.3 m to 261.3 m, the calcitic facies change for a dolomitic facies (C1L). A transitional contact is logged from 261.3 m to 527.4 m. The syenite is dominating but layered with large interval of the dolomitic carbonatite (SC1). After 527.4 m, the carbonatite amount has decreased and the lithology becomes a syenite breccia (SB).

The lanthanides concentrated in the carbonatite and decreased proportionally with the increasing of the syenite. The main mineralized zone returned a value of **2.142% TREO / 196 m** (from 65.3m) including **0.036% HREO / 196 m**.

13.5.4 2012-REE-032

The 2012-REE-032 is situated in the North area of the REE zone (MTME 256282.22: MTMN 5378527.83). It was drilled at 270° (true North) with a dip of -50°. The objectives were to intersect the North-West contact and delimit the REE zone. The overburden is 4.5 m thick. From 4.5 m to 47.6 m, the Trenton limestone covered the carbonatite. From 47.6 m to 52.2 m, the carbonatite conglomerate textured is observed. After the regolith, the carbonatite become a calcitic breccia facies (BRC1L) strongly altered (hematite, chlorite and siderite) to the depth of 88 m. From 88 m to 262 m, a dolomitic carbonatite (C1L) was logged. A breccia facies (BRC1L) succeeded from 262 m to 376 m. From 376 m, the breccia zone continues but syenite enclaves progressively appeared (BRC1S). At 453 m, a section of syenite layered with REE-poor, coarse grained, dolomitic carbonatite facies (SC2) is logged

down to 504 m. The last unit of the hole is a medium grained, massive, REE-poor, dolomitic carbonatite (C2).

The lanthanides are mainly in centimetre scale, purple coloured clusters between the carbonate minerals phases. The main mineralized zone returned a value of **2.122% TREO / 354.4 m** (from 46.7m) including **0.034% HREO / 354.4 m**.

13.5.5 2012-REE-033

The 2012-REE-033 is situated in the South-West area of the drilling zone (MTME 256075.95: MTMN 5378145.06). It was drilled at 031° (true North) with a dip at -70°. The 2012-REE-033 is being part of the deep investigation program. The objectives were to test the positive gravimetric anomaly and investigate the REE potential of the carbonatite at depth. Based on the literatures, the carbonatite complex may have an ultramafic intrusion at the root. The gravimetric anomaly could be generated by this ultramafic intrusion. The hole was drilled down to 1338 m without leaving the REE mineralized carbonatite. The gravimetric anomaly must be explained by another phenomenon. The overburden is 5.1 m thick. From 5.1 m to 43.5 m, the Trenton limestone covered the carbonatite. From 43.5 m to 44.3 m, the carbonatite conglomerate textured is logged. The strongly altered carbonatite breccia (BRC1L) (hematite, chlorite and siderite) is observed down to 93 m. From 93 m to 162 m, a layering of mineralized carbonatite (C1L) and not mineralized carbonatite with enclave of syenite (C1S) is logged. From 162 m to 1338 m, large intervals of massive dolomitic carbonatite facies (C1L) are layered with the brecciated facies (BRC1L).

The lanthanide cluster characteristic changed from 1000 m to deeper. Their grained size increased to pluri-centimetre scale, their texture change from porous to massive and their colour evolve from dark reddish to medium purple. The assays showed an augmentation of the TREO at depth. The increasing of the lanthanides ratio, heavy atomic mass elements, may create the gravimetric anomaly. The 2012-REE-033 returned an outstanding value **2.160% TREO / 1296 m** (from 42m) including **0.032% HREO / 1296 m** of and confirmed the great potential of the REE zone at depth.

13.5.6 2012-REE-034

The 2012-REE-034 is located in the North-East area of the REE zone (MTME 256498.52: MTMN 5378513.03). It was drilled at 211° (true North) with a dip of -77° and a proposal length of 1250 m. The objectives were to test the continuity of the lanthanide mineralization at depth and test the positive gravimetric anomaly based on a historic survey. This anomaly may be produced by an ultramafic intrusion at the base of the St-Honoré carbonatite complex. By drilling on the opposite side of the 2012-REE-033, a scissor pattern was created and tested the probability of different mineralized structures. The overburden is 3.75 m thick. From 3.75 m to 21.40 m, the Trenton limestone covered the carbonatite. The carbonatite begins with a strongly altered (hematite, chlorite and siderite) massive dolomitic carbonatite facies (C1L) down to 75.70 m. From 75.50 m to 1260 m, brecciated carbonatite (BRC1L) and massive dolomitic carbonatite (C1L) are layered in decimetre scale interval. A calcitic carbonatite facies C1LC) is noted from 819 m to 899.40 m.

The 2012-REE-034 stayed in the mineralized carbonatite without intercepting an ultramafic unit. The gravimetric anomaly still unexplained. The mineralogy assemblage and textures change at depth (Figure X and X) and may be explanation for the anomaly that needs to be investigated. The 2012-REE-034 returned an overall value of **1.885% TREO / 1238.6 m** (From 21.4 m) including **0.031% HREO / 1238.6 m**. Like observed in the 2012-REE-033, the lanthanide values slightly increased passed 1000 m deep.

13.5.7 2012-REE-035

The 2012-REE-035 is situated in the South-West area of the drilling zone (MTME 255922.35: MTMN 5378019.43). It was drilled at 028° (true North) with a dip of -55°. The objectives were to delimit the south contact and test the mineralization continuity at depth. The overburden is 9.80 m thick. From 9.80 m to 59 m, the Trenton limestone covered the carbonatite. A weakly altered (hematite and chlorite), lanthanides poor, massive dolomitic carbonatite (C2) is observed on the South contact of the REE zone, from 59 m to 194.2 m. A large mineralized brecciated carbonatite facies (BRC1L) is logged down to 438 m. From there, a layering of mineralized breccia (BRC1L) and massive (C1L) carbonatite is described to the end of the hole at 924 m.

The south contact was traversed at 194.2 m. Mineralization increased over 250 m toward the center of the REE-zone. The 2012-REE-035 returned a value of **2.501% TREO / 486 m** (from 438m) including **0.035% HREO / 486 m** in the best of the REE zone. A large border on the transition zone returned an economical value of 1.315% TREO / 243.8 m.

13.5.8 2012-REE-036

The 2012-REE-036 was previously described down to 450m but was extended later during the definition program. It is located in the South area of the mineralized zone (MTME 256139.63: MTMN 5378055.23). It was drilled at 031° (true North) with a dip of -50°. The objectives were to delimit the south contact and completed a 100 m x 200 m drilling mesh for the scooping study. The extension increased the definition down to the vertical limit of 700m for the pre-feasibility need. The overburden is 5.40 m thick. From 5.40 m to 42.20 m, the Trenton limestone covered the carbonatite. From 42.20 m to 54 m, the REE-poor carbonatite (SC2) contained numerous syenite enclaves and marked the transitional contact with the dolomitic carbonatite (C2). A chlorite alteration is noted down to 177 m. From there to 261.7m, the dolomitic carbonatite (C2) changed to an ankerite carbonatite facies (C1). The lanthanide mineralization appeared around 234m but is found principally in the massive dolomitic carbonatite facies (C1L) starting at 261.7m. A layering of dolomitic breccia and massive facies (BRC1L-C1L) completed the hole down to 900 m.

The REE zone intercepted in the 2012-REE-036 returned a value of **2.141% TREO / 666 m**. (from 234m) including **0.035% HREO / 666 m**. The values increased at depth and the last carbonatite breccia interval returned a value of **2.828% TREO / 133.5 m** (from 766.5 m.) including **0.050% HREO / 133.5 m**. (Figure 3). The surrounding carbonatite (C2 and C1)

on the South contact returned a low value of 0.636% TREO / 191.8 m that may be evaluated in a low grade / high volume mining technic.

Figure 17: 2012-REE-036 high grade zone

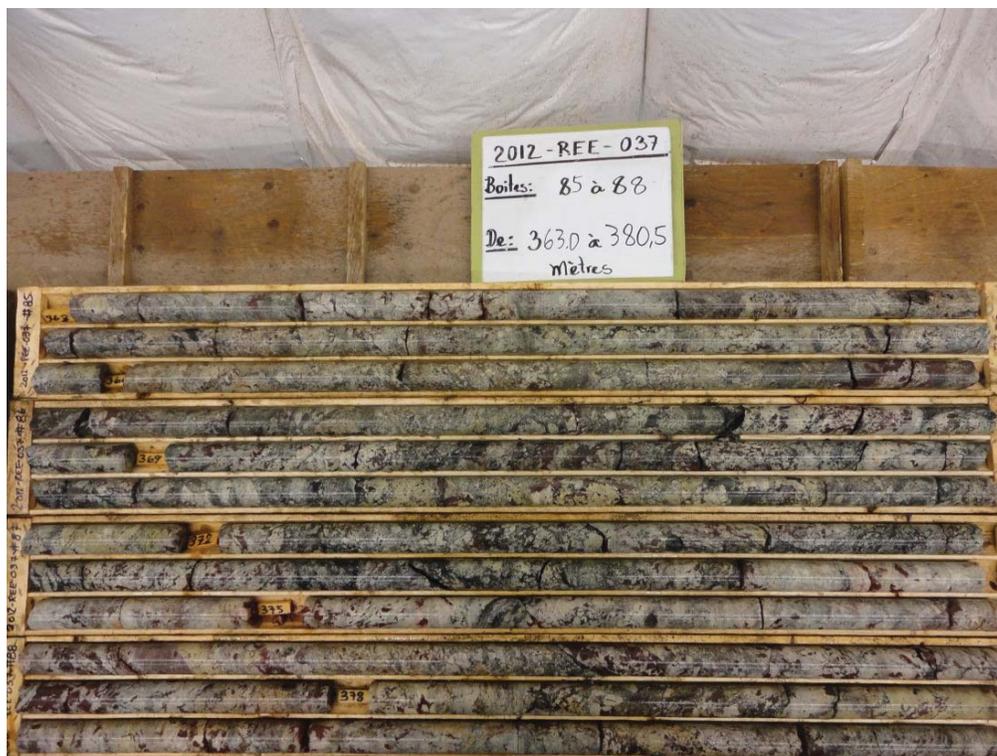

13.5.9 2012-REE-037

The 2012-REE-037 is situated in the Center-West area of the REE zone (MTME 255874.00: MTMN 5378202.00). It was drilled at 028° (true North) with a dip at -50°. The objective was to characterise the core of the REE zone with a drilling pattern of 100m x200m. The overburden is 6.8 m thick. From 6.8 m to 69.5 m, the Trenton limestone covered the carbonatite. The carbonatite begins with a strongly altered breccia facies (BRC1L) (hematite, chlorite and siderite) down to the depth of 132.2 m. From 132.2 m, the paleo-weathering alteration disappeared and the fresh carbonatite breccia facies (BRC1L) is logged down to 321 m. From 321 m to 798m, large interval of breccia (BRC1L) and massive (C1L) (Figure 17) carbonatite facies are layered.

The hole stays in the mineralized carbonatite and returned value of **2.263% TREO / 728.5 m** (from 69.5 m) including **0.031% HREO / 728.5 m**.

Figure 18: Lanthanide mineralized carbonatite (CIL), 2012-REE-037

13.5.10 2012-REE-038

The 2012-REE-038 is situated in the South-East of the REE zone (MTME 256218.97: MTMN 5378001). It was drilled at 031° (true North) with a dip at -50°. The objectives were to continue the drilling pattern of 100m x 200m and delimit the South contact. The overburden is 10.20 m thick. From 10.20 m to 38 m, the Trenton limestone covered the carbonatite. The carbonatite begin with a REE-poor dolomitic breccia facies (BRC2) down to 183 m. From 183 m to 252 m, a massive, medium grain textured calcitic facies (CCA) is observed. An ankeritic and dolomitic breccia facies (BRC1) followed down to 373.6 m. From there, the dolomitic carbonatite become massive (CIL).

The mineralization appeared at the depth of 357 m in a breccia facies. The south contact was limited by the low grade carbonatite returning a value of 0.600% TREO / 319 m (from 38 m.). The REE zone returned a value of **1.077% TREO / 45 m** (from 357 m) including **0.016% HREO / 45 m**.

13.5.11 2012-REE-039

The 2012-REE-039 is situated at the South-West of the REE zone (MTME 255797.05: MTMN 5378244.16). It was drilled at 028° (true North) with a dip of -50°. The objective was to complete a definition drilling pattern of 100m x 200m. The overburden is 15.90 m thick. From 15.90 m to 55.70 m, the Trenton limestone covered the carbonatite. The

carbonatite begins with a strongly altered breccia facies (hematite, chlorite and siderite) (BRC1L) down to 98 m. The alteration decreased (hematite and chlorite) down to 207 m. From 207 m to 564 m, the dolomitic mineralized breccia facies is logged (BRC1L).

The mineralisation is observed all along the hole but increased at depth. The 2012-REE-039 returned a value of **1.802% TREO / 508.3 m** (from 55.7 m) including **0.031% HREO / 508.3 m**.

13.5.12 2012-REE-040

The 2012-REE-040 is situated at the center east of the REE zone (MTME 256340.87; MTMN 5378225.07). It was drilled at 031° (true North) with a dip of -50°. The objectives were to increase the REE definition by following a drilling mesh of 100m x100m and intersect the North contact in depth. The overburden is 8.60 m thick. From 8.60 m to 11.80 m, the Trenton limestone covered the carbonatite. A massive calcitic and dolomitic carbonatite facies (C1L) strongly altered (hematite, chlorite and siderite) is logged down to 102.70 m. A small breccia facies (BRC1L) cut the massive facies from 102.70 m to 142.40 m. From 142.40 m to 729 m, there is a layering between massive dolomitic carbonatite and calcitic carbonatite (C10 and C1C). Two breccias facies, from 405.30 m to 430.80 m and from 543 m to 600.50 m, disturbed the massive textured intervals.

The mineralization is homogeneous all along the hole. The 2012-REE-040 returned a value of **2.134% TREO / 717.2 m** (from 11.8 m) including **0.028% HREO / 717.2.3 m**.

13.5.13 2012-REE-041

The 2012-REE-041 is situated in the center area of the REE zone (MTME 256292.71; MTMN 5378307.19). It was drilled at 028° (true North) with a dip of -50°. The objectives were to complete the drilling pattern of 100m x 100m and intersect the north contact at depth. The overburden is 6.80 m thick. From 6.80 m to 36.20 m, The Trenton limestone covered the carbonatite. From 36.20m, the calcitic breccia carbonatite facies (BRC1C) is strongly altered (hematite, chlorite and siderite) down to 99.70 m. The same breccia facies becomes less altered down to 342 m. From 342 m to 434.10 m, a transition zone is noted where the carbonatite progressively changed from a calcitic to a dolomitic facies. From 434.10 m to 734.10 m, the dolomitic carbonatite (C1L) dominated but is cut by a large breccia facies (BRC1) between 539.70 m to 622.20. From 734.10 m to 774, the dolomitic breccia carbonatite facies completed the hole.

The lanthanide mineralization is transitionally decreasing in the lower part of the hole marking the North contact at depth with the not mineralized carbonatite. The hole 2012-REE-041 returned an overall value of **1.798% TREO / 697.9m** (from 36.2m) **including 0.029% HREO / 697.9m**. The best interval, without not mineralized breccia facies, returned a value of **1.987% TREO / 503.5m** (from 36.2m) **including 0.32% HREO / 503.5ms**.

13.5.14 2012-REE-042

The 2012-REE-042 is situated in the center area of the REE zone (MTME 256208.17; MTMN 5378339.99). It was drilled at 029° (true North) with a dip of -52°. The objective

was to complete a drilling pattern of 100m x100m for the pre-feasibility study. The overburden is 7.40 m thick. From 7.40 m to 41.60 m, the Trenton limestone covered the carbonatite. A carbonatite breccia textured facies (BRC1L), strongly altered by the paleo-weathering (hematite, chlorite and siderite) is logged down to 107.30 m. From 107.30 m to 975 m, there is a layering of breccia facies (BRC1L) and massive facies (C1L) of the dolomitic carbonatite. Between 213.70 m to 291.70 m, both facies becomes more calcitic than dolomitic composed. The North contact was traversed at the depth of 975 m. From there to 992 m, a medium grained, massive textured, and lanthanide poor dolomitic carbonatite (C5) is observed.

The 2012-REE-042 returned an overall value of **1.652% TREO / 950.4 m** (from 41.6 m) including **0.26% HREO / 950.4 m**. The last 383 m are progressing in the transition zone between the mineralized and not mineralized carbonatite and have a diluting effect on the TREO value. The best interval in the core of the REE zone returned a value of **1.934% TREO / 567.4 m** (from 41.6m) including **0.33% HREO / 567.4 m**.

13.5.15 2012-REE-043

The 2012-REE-043 is situated in the North-West area of the REE zone (MTME 256041.58: MTMN 5378449.20). It was drilled at 031° (true North) with a dip of -52°. The objective was to complete a drilling mesh of 100m x100m for the pre-feasibility study. The overburden is 7.10 m thick. From 7.10 m to 57 m, the Trenton limestone covered the carbonatite. A massive calcitic carbonatite facies (C1C), strongly altered (hematite, chlorite and siderite) is logged down to 125 m. Further, the same calcitic facies continues but with a decreasing of the paleo-weathering alteration. The massive calcitic facies continues down to 183.40 m. From 183.40 m to 723 m, a carbonatite breccia facies (BRC1L) dominated. The proportion of matrix is variable from 20% to 60%. The grain size decreased when the breccia textures increased. An interval of massive dolomitic carbonatite facies (C1L) is logged between 445.60 m and 504.80 m. The hole finished in the mineralized, massive dolomitic carbonatite (C1L) down to 743m.

Even if the hole finished in the mineralization, the analyses showed a decrease of the lanthanide values. It is explained by the transitional contact between the REE bearing carbonatite and the surrounding carbonatite and syenite complex. The 2012-REE-043 returned an overall value of **2.066% TREO / 684 m** (from 57 m) including **0.035% HREO / 684 m**.

13.5.16 2012-REE-044

The 2012-REE-044 is situated in the North area of the REE zone (MTME 256218.95: MTMN 5378573.87). It was drilled at 031° (true North) with a dip of -53°. The objectives were to intersect the north contact in deep and complete the 100 m x 100 m drilling mesh for the pre-feasibility. The overburden is 21.60 m thick. From 21.60 m to 37.30 m, the Trenton limestone covered the carbonatite. A brecciated calcitic carbonatite facies (BRC1LC) strongly altered (hematite, chlorite and siderite) is described down to 53.30 m. From 53.30 m to 82.30 m, the calcite is substituted by the dolomite in the sub-surface altered facies

(BRC1L). The fresh carbonatite breccia (BRC1L) continues down to 381 m. From 381 m to 516 m, the texture changed from breccia to massive dolomitic carbonatite (C1L).

The hole 2012-REE-044 did not leave the mineralized zone. The vertical projection of the contact in the 2011-RRR-023 should have been traversed around 450 m depth. Assays results returned homogeneous lanthanides values all along the hole. **1.834% TREO / 480.7 m** (from 35.3) including **0.025% HREO / 480.7 m**. The weathered facies is enriched in REE and returned a value of 2.328% TREO / 47 m (from 35.3m).

13.5.17 2012-REE-045

The 2012-REE-045 is situated in the North area of the REE zone (MTME 256305.52: MTMN 5378523.95). It was drilled at 031° (true North) with a dip of -53°. The objectives were to intersect the north contact at depth and continue the 100m x 100m mesh for the pre-feasibility. The overburden is 2.70 m thick. From 2.70 m to 52 m, the Trenton limestone covered the carbonatite. The carbonatite begins in a strongly altered calcitic breccia facies (BRC1LC). The paleo-weathering alteration is composed of hematite, chlorite and siderite. The colour of the altered carbonatite varied in the warm shade of red and yellow. The calcitic breccia facies continue down to 114 m. From 114 m to 498 m, massive dolomitic facies (C1L) are layered with breccia facies (BRC1L).

The hole did not intercept the not mineralized carbonatite located on the north contact but the assays showed a lower concentration of lanthanide after 378 m depth. Even if the mineralisation decreased, the Northern transition contact can be considerate economically. The 2012-REE-045 returned an overall value of **1.701% TREO / 443 m** (From 52m) including **0.027% HREO / 443 m** but the best interval without the transitional contact returned 1.976% TREO / 323 m (from 52m) including 0.031% HREO / 323 m.

13.5.18 2012-REE-046

The 2012-REE-046 is situated in the middle-south area of the REE zone (MTME 256110.67: MTMN 5378197.12). It was drilled at 031° (true North) with a dip of -60°. The objectives were to create a drilling pattern of 100m x100m and test the continuity of the lanthanide mineralisation at depth. The overburden is 5.70 m thick. From 5.70 m to 32 m, The Trenton limestone covered the carbonatite. A strongly altered breccia facies carbonatite (BRC1L) (hematite, chlorite and siderite) is described down to 54 m. From there, the alteration disappeared and the fresh breccia facies continues down to 444 m. From 444 m to 873 m, massive dolomitic (C1L) and breccia carbonatite (BRC1L) facies are layered. Large intervals are more calcitic composed (C1LC and BRC1LC), from 444 m to 480 m and from 673.40 m to 714 m.

The 2012-REE-046 returned a homogeneous value all along the hole of **2.064% TREO / 873 m**. (from 32m.) including **0.037% HREO / 873 m**. This great interval confirmed the homogeneous distribution of the lanthanides in the REE zone.

13.5.19 2012-REE-047

The 2012-REE-047 is situated in the middle-South area of the REE zone (MTME 256014.15: MTMN 5378232.69). It was drilled at 029° (true North) with a dip at -54°. The objectives were to create a drilling pattern of 100m x100m and verify the mineralization continuity at depth. The overburden is 6.40 m thick. From 6.40 m to 51 m, the Trenton limestone covered the carbonatite. The carbonatite begins with a strongly altered (hematite, chlorite and siderite) breccia facies (BRC1L) down to 84.40 m. The alteration decreased and the breccia facies (BRC1L) continues down to 210.80 m. From 210.80 m to 903 m, there is a layering of massive facies (C1L) and breccia facies (BRC1L) in the mineralized dolomitic carbonatite.

The 2012-REE-047 did not leave the mineralized body and returned a homogeneous value of **2.251% TREO / 853 m.** (from 50m.) including **0.035% HREO / 853 m.** In the previous results, the altered layer is usually enriched in lanthanide but the 2012-REE-047 showed depletion compare to the fresh carbonatite (Table 4). The relation between the lanthanide concentration and the weathered layer must be investigated.

13.5.20 2012-REE-048

The 2012-REE-048 is situated in the North-East of the REE zone (MTME 256396.27: MTMN 5378483.95). It was drill at 031° (true North) with a dip at -50°. The objectives were to continue the drilling pattern of 100m x100m and intersect the North contact at depth. The overburden is 3.20 m thick. From 3.20 m to 44 m, the Trenton limestone covered the carbonatite. The calcitic breccia carbonatite facies (BRC1LC) was affected, down to 105 m, by the paleo-weathering alteration characterised by the pervasive hematite, the chlorite and the siderite. From 105 m to 351m, the dolomitic carbonatite was layered in breccia (BRC1L) and massive (C1L) facies. From 351 to 567 m, the lithology was described has the previous interval but the lanthanides contain decreased. The low grading carbonatite is usually called the transition zone. At 567m, the North contact was intercepted. From there, a medium grained carbonatite (C5) without lanthanides was logged.

The main mineralized zone returned a value of **2.366% TREO / 307 m.** (from 44m.) including **0.041% HREO / 307 m.** The transition zone returned a value of 1.259% TREO / 216 m. (from 351). Even if the grade is lower in the transition zone, it must be evaluated for a potential lanthanide resource.

13.5.21 2012-REE-049

The 2012-REE-049 is situated in the middle-South area of the drilling zone (MTME 256188.71: MTMN 5378134.72). It was drilled at 029° (true North) with a dip of -50°. The objectives were to create a drilling pattern of 100m x100m, to intersect the South contact and verify the mineralization extension at depth. The overburden is 15 m thick. From 15 m to 36.90 m, the Trenton limestone covered the carbonatite. From 36.90 m to 144.50 m, a coarse grained, REE-poor carbonatite facies (C2) was logged. This facies is weakly altered (hematite, siderite and chlorite) by the paleo-weathering. From 144.50 m to 175.60 m, a calcitic massive carbonatite facies is described (C1C). The South contact was intercepted at 175.6 m and is characterised by the increase of the lanthanide mineralization. From 175.60 m

to 304.60 m, a mineralized calcitic breccia facies is observed (BRC1LC). From 304.60 m to 900 m, pluri-metre scale massive dolomitic carbonatite breccia facies and massive are layered. Between 614 m and 672 m the dolomitic carbonatite was replaced by a calcitic facies.

In the 2012-REE-049, the carbonatite at the South contact (C2) returned a value of 1.030% TREO / 138.7 m. (from 36.9 m.). The main REE zone returned a excellent value of **2.172% TREO / 724.4 m.** (From 175.6) including **0.035% HREO / 724.4 m.** The south contact was delimited and the lanthanides mineralization still open at depth.

13.5.22 2012-REE-050

The 2012-REE-050 is situated on the North-East Edge of the REE zone (MTME 256449.65: MTMN 5378369.66). It was drilled at 031° (true North) with a dip of -50°. The objectives were to intersect the North contact at depth and completed the 100m x100 m drilling mesh. The overburden is 6.8 m thick. From 6.8 m to 15.3 m, the Trenton limestone covered the carbonatite. The carbonatite, down to 69 m., was described like a strongly altered (hematite, chlorite and siderite) breccia facies poor in rare earth minerals (3-4%) (BRC1). From 69 m to 102 m, the same facies continue but the alteration stopped and the percentage of rare earth minerals increased (5%) (BRC1L). From 102 to 159.3 m, a massive dolomitic carbonatite facies (C1L), composed of 5% rare earth minerals (in cluster and disseminated) and 2-3% of disseminated pyrite, is described. From 159.3 m to 177 m, a breccia facies (BRC1L) containing 1-2% of disseminated pyrite (locally in cluster) and 6% of rare earth minerals in cluster or disseminated is logged. From 177 m to 284.7 m, the massive dolomitic carbonatite facies (C1L) contains an average of 6% of rare earth minerals and 2-3% of disseminated pyrite locally in mm/cm scale clusters. From 284.7 to 365.5 m., the breccia facies contained 1-2% of disseminated pyrite (locally in mm/cm scale clusters) and 7% of rare earth minerals (disseminated and in small clusters). From 365.5m to 428.5m, the same breccia facies is observed but the rare earth minerals decrease (3-4%). From 428.5m to 552m, the massive dolomitic carbonatite facies contained an average of 5-6% of rare earth minerals (in cluster and disseminated), apatite (2-4% in stringers) and 2-3% of disseminated pyrite (locally in mm/cm cluster). From 552m to 598.5m, the same massive dolomitic carbonatite facies continued but the percentage of rare earth minerals decreased, the apatite stringer increased (3%) and the disseminated pyrite stayed the same (2-3%).

Assays values delimited the North contact between the mineralized carbonatite and the surrounding carbonatite. The contact is transitional and lanthanides values decreased progressively but small lanthanides enriched layer created punctual peaks. The 2012-REE-050 returned an overall value of 1.734% TREO / 583.2m (from 15.3m) including 0.026% HREO / 583.2m. The main mineralized core returned a value of **1.985% TREO / 359.5m** (from 69m) including **0.029% HREO / 359.5m.** The surrounding carbonatite (C2) was also weakly mineralized and returned not negligible values of 1.203% TREO / 170m. The mining potential of the nearby carbonatite should be seriously evaluated.

13.5.23 2012-REE-051

The 2012-REE-051 is situated on the North-East of the REE zone (MTME 256498.54: MTMN 5378461.51). It was drilled at 031° (true North) with a dip of -50°. The objectives were to intersect the North contact at depth and complete the 100m x100m drilling mesh. The overburden is 3 m thick. From 3m to 17.6m, the Trenton limestone covered the carbonatite. A carbonatite breccia facies (BRC1L), strongly altered (hematite, chlorite and siderite) and composed of 5% rare earth minerals, was logged down to 108.7 m. From 108.7m to 192 m, the same facies, without the alteration, have a similar percentage of rare earth minerals. From 192 to 241.4 m, a massive dolomitic carbonatite facies (C1L) with 5-6% rare earth minerals (in cluster and disseminated) and 2-3% disseminated pyrite is observed. A dolomitic breccia facies followed down to 327.5m. This facies contained 1-2% pyrite and 2-3% rare earth minerals in cluster. Locally, there are massive carbonatite (C1L) enriched in REE minerals clusters (5-6%). From 327.5 m to 351 m, a massive dolomitic carbonatite facies closed the hole. Rare earth minerals decreased (average of 2-3%).

Once again, the hole achieved is objective of delimiting the North contact. Assays results showed a net depletion of the lanthanides from 261m. The hole 2012-REE-051 returned an overall value of 1.944% TREO / 333.4m (from 17.6m) including 0.032% HREO / 333.4m. the sub-surface altered carbonatite is enriched in TREO and de main mineralized carbonatite returned a value of **1.985% TREO / 152.3m** (from 108.7m) including **0.031% HREO / 152.3m**.

13.5.24 2012-REE-052

The 2012-REE-052 is located on the South-East of the REE zone (MTME 256276.22: MTMN 5378083.66). It was drilled at 031° (true north) with a dip at -50°. The objective were to intersect the South contact at depth and complete a 100m x100m drilling mesh. The overburden is 3 m thick. From 3 m to 16.5 m, the Trenton limestone covered the carbonatite. A massive coarse grained dolomitic carbonatite facies (C2S), depleted in rare earth minerals, with over 5% of syenitic enclave and 2-3% apatite stringer, is logged down to 176 m. From 176 m to 264 m, a carbonatite breccia facies (BRC1) with 3% of rare earth minerals clusters and 2-3% of apatite stringer is described. From 264 m, the massive dolomitic carbonate facies (C1) was poor in rare earth minerals (2-3% disseminated clusters), composed of 2-3% disseminated pyrite and 2-4% apatite stringers. From 399 m and down to 492 m, the breccia facies (BRC1) returned. This facies contained 1-2% disseminated pyrite disseminated (locally in clusters) and 2-3% of rare earth minerals in clusters. Locally, there is massive layers of carbonate with rare earth minerals clusters reaching 5-6% in proportion. From 492 m to 634.5 m, the same breccia facies (BRC1L) is logged but the percentage of rare earth minerals increased (an average of 5-6%) when the pyrite and the apatite decrease. From 634.5 m to 767.5 m, a massive calcitic carbonate facies (C1LC), whit 5-6% (locally 8%) of rare earth minerals. The mineralization is associated with the barite and the halite. From 767.5 m to 900 m, the dolomitic breccia facies (BRC1L) composed of 7% disseminated rare earth minerals in clusters is logged to the end of the hole.

The first interval drilled was composed of the carbonatite (C2) from the transition zone. The REE contain increased toward the core and the value returned is 1.185% TREO / 274.5m (from 16.5m). In the REE zone, where the mineralization is concentrated, the value returned is **1.844% TREO / 609m** (from 291m) including **0.031% HREO / 609m**.

13.5.25 2012-REE-053

The 2012-REE-053 is located on the East of the REE zone (MTME 256567.96: MTMN 5378372.47). It was drilled at 031° (true north) with a dip of -50°. The objectives were to intersect the North contact at depth and completed the 100m x100m drilling mesh for the pre-feasibility study. The overburden is 3.5m thick. From 3.5m to 28m, the Trenton limestone covered the carbonatite. The upper part of the dolomitic carbonatite was massive textured, coarse grained, strongly altered (hematite, chlorite and siderite) and poorly mineralized down to 67.5 m. From 67.5 m to 139.5 m, the same facies continued with an incursion of lanthanides (3%) disseminated between carbonates minerals and rarely in clusters. Apatite stringers (5-7%) and disseminated pyrite (1-2%) are noted. From 139.5m to 175.3m, the massive facies changed for a breccia facies (BRC1) poor in REE minerals (2% disseminated), 2-3% disseminated pyrite and 4-7% apatite stringer. From 175.3m to 207m, a massive dolomitic carbonate (C1L) containing disseminated pyrite (1-2%) and rare earth minerals in cluster (2-3%) was logged. Locally, massive carbonates with rare earth minerals clusters (5-6%) are observed. From 207 m to 279 m, the massive dolomitic carbonatite is enriched in rare earth minerals (an average of 6-8%) and depleted in apatite. From 279 m to 369 m, the breccia facies was poorly mineralized (3-5% lanthanides). In this interval a clear relationship with the barite was noticed. A massive, coarse grained dolomitic carbonatite depleted in REE minerals completed the hole down to 453m.

The 2012-REE-053 returned a value of 1.501% TREO / 425m (from 28m) including 0.024 HREO / 425m. Excluding the surrounding carbonatite, the core zone returned a value of **1.658% TREO / 257m** (from 28m) including **0.029% HREO / 257m**. The hole delimited the North-East corner of the REE zone by its lower average value compared to the middle area.

13.5.26 2012-REE-054

The 2012-REE-054 is located on the South-East area of the REE zone (MTME 256265.76: MTMN 5377958.18). It was drilled at 033° (true north) with a dip of -50°. The objectives were to intersect the South contact at depth, to delimit the REE zone and also completed the 100m X 100m drilling mesh. The overburden is 9.8 m thick. From 9.8 m to 55 m, the Trenton limestone covered the carbonatite. The carbonatite begins with a massive textured and a coarse grained dolomitic facies (C2), poor in rare earth minerals and strongly altered (hematite, chlorite and siderite) down to 117 m. From 117 m to 223 m, the paleo-weathering alteration disappeared. Apatite stringer (5-8%) and disseminated pyrite (1-2%) are logged. From 223 m to 256.5 m, a syenite enclave is dislocated by the massive coarse grained dolomitic carbonate facies. From 256.5 m to 519 m, the same C2 facies, low in rare earth minerals returned. The apatite content seems to decrease with depth. From 519 m to the

end of hole, 900 m, a massive dolomitic facies (C1) is logged. This facies locally contained rare earth minerals but non continuity was observed.

The hole did not intersect the REE zone. Assays results reflect the low rare earth minerals content. The coarse grained dolomitic facies (C2) returned a value of 0.539% TREO / 848m (from 52m) including 0.014% HREO / 848m. The low grading transition zone, C2, may have an economical interest depending on the economical context and the exploitation method choose.

13.5.27 2012-REE-055

The 2012-REE-055 is situated on the North-West area of the REE zone (MTME 256087.07: MTMN 5378531.73). It was drilled at 301° (true north) with a dip of -45°. The objective was to intersect the West contact at depth for delimiting the REE zone. The overburden is 12.5m thick. From 12.5m to 57m, the Trenton limestone covered the carbonatite. A massive dolomitic carbonatite facies (C1L) rich in rare earth minerals and strongly altered (hematite, chlorite and siderite) is logged down to 99 m. From 99m to 159m, the same facies without the alteration contained apatite stringer (5-8%) and disseminated pyrite (1-2%). From 159m to 276m, log described a breccia facies with a rare earth minerals percentage of decreasing and an increasing amount of syenite enclaves.

The 2012-REE-055 intercepted the west contact has plan. It returned an overall value of 1.747% TREO / 216m (from 57m) including 0.029% HREO / 216m. The main REE zone, intercepted in the upper part of the hole returned a value of **1.900% TREO / 147m** (from 57m) including **0.032% HREO / 147m**.

13.5.28 2012-REE-056

The 2012-REE-056 is located on the North-West area of the REE zone (MTME 256087.47: MTMN 5378531.53). The same set-up was used to drill the 2012-REE-055 and 2012-REE-056. It was drilled at 301° (true north) with a dip of -75°. The objective was to intersect the West contact at depth. The overburden is 9 m thick. From 9 m to 43.5 m, the Trenton limestone covered the carbonatite. From 43.5m and down to 108m, a mineralized carbonatite breccia facies (BRC1L) is logged. The sub- surface alteration (hematite, chlorite and siderite) is observed. From 108 m to 147 m, the same facies is noted. The rare earth minerals content decreased toward depth. There average proportion varied around 4%) and are associated to disseminated pyrite clusters (1-2%). A calcitic facies (BRC1C) is logged from 147 m to 193.1 m. The same breccia facies, but no calcitic, is intersected down to 516 m. The REEs minerals content seems to increase with the degree of breccia intensity. A light decrease of REE is visible from 285 to 351 m. Other mineralisation are pyrite (1-2% in disseminated cluster) and apatite (2-5% in stringer). From 516 m to 549.6 m, many syenite enclaves (75%) are observed. This changed mark the contact between the REE zone and the surrounding transition zone composed of massive dolomitic coarse grain carbonatite (C2).

The REE zone returned an excellent value of **2.242% TREO / 475.5m** (from 43.5m) including **0.033% HREO / 475.5m**. The small interval drilled in the transition returned also a good value of 1.297% TREO / 30m (from 519m).

13.5.29 2012-REE-057

The 2012-REE-057 is located on the South-East area of the REE zone (MTME 256359.05: MTMN 5378016.91). It was drilled at 031° (true north) with a dip of -50°. The objectives were to intersect the South contact at depth and delimit the REE zone. The overburden is 12.7 m thick. From 12.7 m to 41.6 m, the Trenton limestone covered the carbonatite. A massive textured, coarse grained carbonatite (C2), poor in Lanthanide is mainly logged down to the end of hole, 643.4m. There is locally presence of Lanthanides (trace). Many stringers of apatite (4-8%) and disseminated pyrite cluster (1-3%) are observed. Few syenites enclaves are disseminated through the facies. The hole never reached the mineralized REE zone. The contact is slightly off set on the West and parallel to the drilling direction.

The 2012-REE-057 did not leaves the transition zone and returned a value of 0.643% TREO / 601.8m (from 41.6m) including 0.018% HREO / 601.8m. The REEs distribution is homogeneous with the 2012-REE-054 and 2012-REE-059 values drilled on the same section (2800E).

13.5.30 2012-REE-058

The 2012-REE-058 is located on the West area of the REE zone (MTME 255998.77: MTMN 5378352.29). It was drilled at 301° (true north) with a dip of -50°. The objective was to intersect the west contact at depth. The overburden is 5.9 m thick. From 5.9 m to 54 m, the Trenton limestone covered the carbonatite. The first interval of carbonatite facies is interpreted as the regolith, a hematite, chlorite and siderite strongly altered facies. From 54 m to 111 m, a breccia facies strongly altered (hematite, chlorite and siderite). It is difficult to determinate mineral phase. From 111 m to 149 m, a massive dolomitic facies (C1L), rich in REEs minerals (5%), with disseminated pyrite and locally apatite stringers is logged. At 149 m, the contact with the transition zone is traversed. A syenite enclave's rich breccia facies (SC2) composed of 60-70 % syenite and 30-40% of carbonatite (C2) is described. This facies is depleted in REEs minerals but included disseminated pyrite (1-2% and apatite stringer (3%). From 207 m to 351 m, the syenite enclaves proportion decreased (4-5%).

The REEs zone interval returned a value of **1.319% TREO / 95m** (from 54m) including **0.032 HREO / 95m** when the transition zone returned a value of 0.800% TREO / 202m (from 149m).

13.5.31 2012-REE-059

The 2012-REE-059 is located on the South-East area of the REE zone (MTME 256404.94: MTMN 5378111.15). It was drilled at 031° (true north) with a dip of -50°. The objective was to intersect the South contact at depth. It was plan to begin in the transition zone and finish in the REE zone. The overburden is 12.2 m thick. From 12.2 m to 22.3 m, the Trenton limestone covered the carbonatite. The first facies encounter was a massive textured and a coarse grained carbonatite facies (C2). There is few syenite enclaves through this facies

except between 197.4 m and 208 m where the syenite (SC2) become the main lithology. The mineralisation is composed of apatite stringers (4-8%), pyrite clusters (1-3%), disseminated REE minerals (trace) and disseminated pyrochlore (trace to 1%). From 600 m to 892.6 m, a mine facies (C3NA) was recognized, but strongly brecciated. Layer of massive textured and coarse grained carbonatite faices (C2) are mixed with the syenite enclaves. The Pyrochlore crystal are visible in the C3NA facies. Other mineralisations are composed of pyrite (1-2% disseminated and locally in cluster), apatite (8% stringer) and disseminated REE (trace).

The C2 facies is homogeneous and returned a value of 0.576% TREO / 546.3m (from 20.7m) including 0.018% HREO / 546.3m. The mine facies (C3NA) is slightly enriched in REEs compared to the transition zone and returned a value of 0.819% TREO / 325.6m.

13.5.32 2012-REE-060

The 2012-REE-060 is located in the West area of the REE zone (MTME 255999.33: MTMN 5378351.98). It was drilled on the same set-up of the 2012-REE-055. It was drilled at 301° (true north) with a dip of -75°. The objective was to intersect the West contact at depth. The overburden is 4.4 m thick. From 4.4 m to 30.8 m, the Trenton limestone covered the carbonatite. The breccia facies (BRC1L), rich in rare earth minerals, strongly altered (hematite, chlorite and siderite) is logged down to 86 m. From 86 m to 471 m, the same facies is encounter but without the alteration. From 471 m to 500 m, the REE amount is decreasing (1-3% disseminated) when the syenite enclaves amount increased (10-20%). The apparition of the syenite mark the contact with the transition zone.

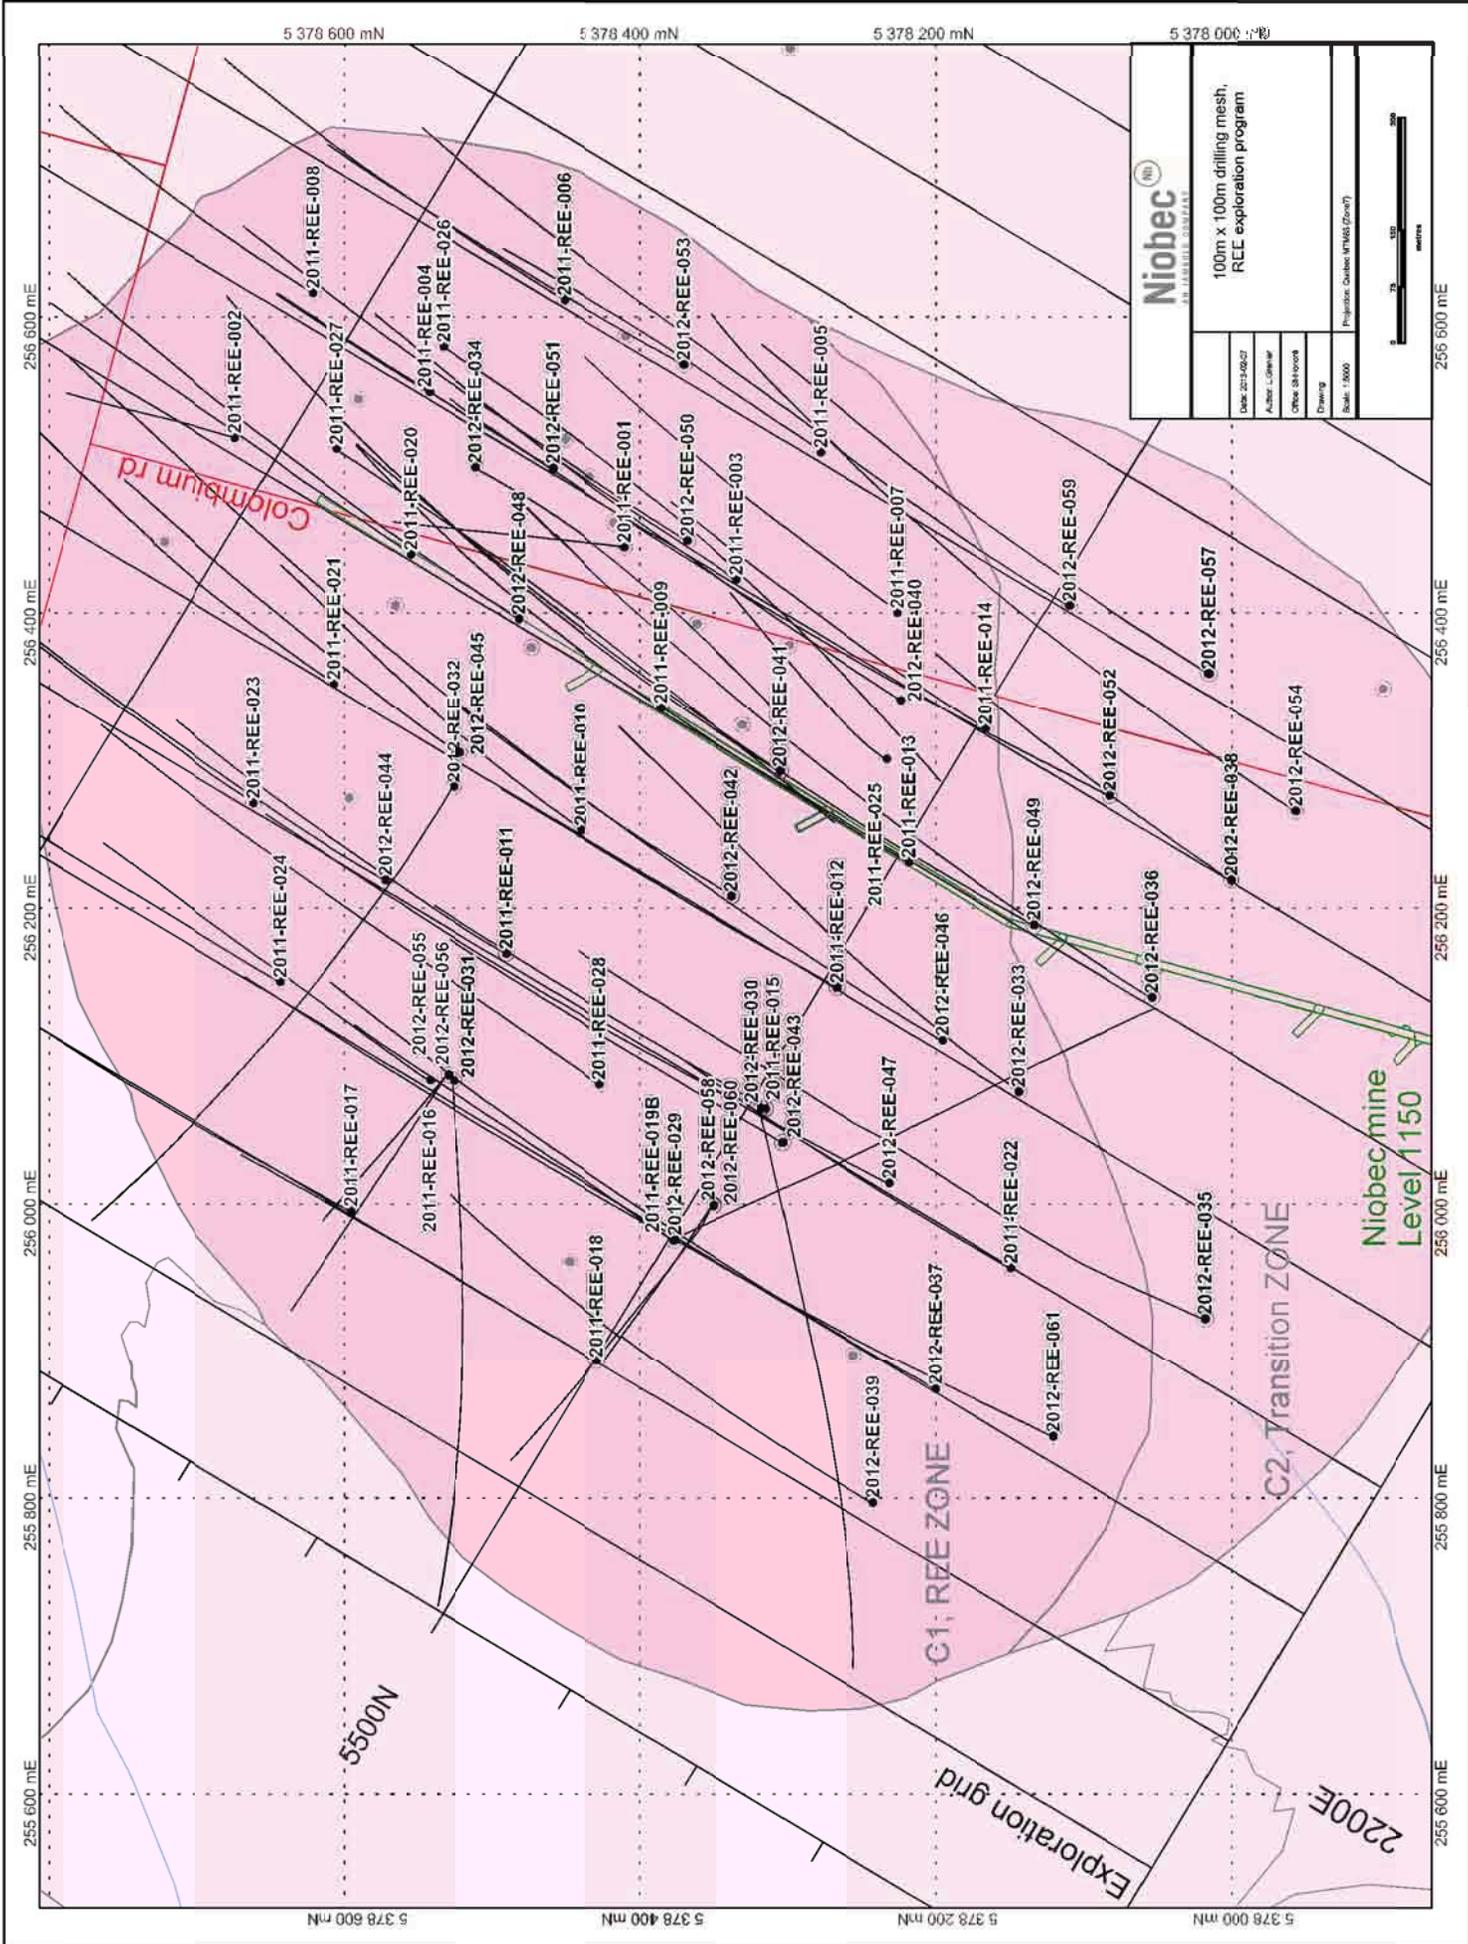

The first interval, drilled in the REE zone returned a value of **1.840% TREO / 428.2m** (from 30.8m) including **0.033% HREO / 428.2m**. The transition zone returned a value of 0.913% TREO / 41m. Once again, the assay results confirmed the grade diminution in the transition but show his economic potential.

13.5.33 2012-REE-061

The 2012-REE-061 is located on the South-West area of the REE zone (MTME 255841.72: MTMN 5378122.17). It was drilled at 30.9° (true north) with a dip of -59.9°. The objectives were to test the depth extension of the lanthanides high grade zone returned in the 2012-REE-037. The overburden is 6.7 m thick. From 46.7 m to 57.6 m, the Trenton limestone covered the carbonatite. The regolith (hematite, chlorite and siderite alteration) is breccia textured and depleted of lanthanides (BRC1). From 108.5 m, the altered facies is followed by a fresh breccia facies (BRC1). From 372 m to 546 m, the REE mineralization begin in a massive carbonatite facies (C1L). Breccia component (10%) are omnipresent. The lanthanides mineralization (7%) is found in purple coloured, centimetre scale cluster in the massive facies and disseminated in the breccia facies. From 546 m to 603 m, the breccia dominate (80%). The lanthanides mineralization (7%) is principally disseminated, but some centimetre scale clusters are still visible. From 603m to 687 m, the breccia decreased (30%) and is replaced by the massive carbonatite facies (C1L). The mineralization of lanthanides (6%) includes disseminated apatite. From 687 m to 858 m, breccia facies dominate. The breccia matrix composed of halite and chlorite (locally, there is dark coloured matrix). The sub-angular

fragments are composed of dolomite. The majority of the mineralization is disseminated in the breccia. Locally, syenite enclaves are noted. From 858 m to 945 m, the lanthanides decrease abruptly to 1-2% (BRC1). There still few zones mineralized (metrics zones of C1L). Apatite stringer increased. From 945 m to 997.3 m, syenite dominated (SC2). There is massive carbonatite (30%), with 2-3% lanthanides, mixed with syenite. From 997.3 m to 1076.1 m, a massive carbonatite (C2) is logged. In this interval, the syenite enclave amount decreased, apatite stringer still noted, and ,locally, presence of Niobium facies (C3NA) are observed. From 1076.1 m to 1191 m, a breccia facies, depleted of lanthanides (BRC1) finished the hole.

The REE zone was intercepted in the middle of the hole. The high grade zone was confirmed. It returned a value of **2.728% TREO / 513m** (from 342m) including **0.033% HREO / 513m**. The South transition zone, intercepted previously, returned a value of 1.088% TREO / 287.3 (from 54.7m) and the North transition zone returned a value of 0.989% TREO / 316m (from 855).

13.7 Drill holes results, 2012 REE exploration program.

The 2012 exploration and definition drilling program confirmed the REE mineralisation distribution homogeneity. The 100 x 100 metres drilling mesh performed help the geology team to define the core of the REE rich carbonatite and the relationship with the surrounding units. The transition zone returned interesting results on large interval and must be evaluated for its economic value.

The new 100m x 100m drilling pattern increased the resource confidence from sub-surface to 350m below. The 2011 inferred resources were all transformed in indicated resources. The drilling accuracy from 350m to 700m, 100m x 200m drilling mesh, added inferred resources at depth. Even if the resources calculation was limited to 700m, the deepest holes confirmed the mineralisation continuity down to 1200m below surface.

Mineralogical studies are under progress to evaluate the REEs mineral affinities and distribution. The 2012 drill hole reached deeper than ever historically. Preliminary interpretation based on the core description and the Assays results show a relationship between the REEs mineral content and the deepness. Pass 1000m deep, the texture of the hosting carbonatite and the lanthanide minerals change. Simultaneously, the average REE content slightly increased. This observation are currently investigated and tested by a master project conjointly realised by IAMGOLD-Niobec and the UQAC University.

The deep holes also tested gravimetric anomaly hypothesis. In 2011, based on theory projection, an ultra-mafic source, located at the base of the Saint-Honoré carbonatite complex, was interpreted to be the explanation of the gravimetric anomaly. Excepted few angular enclaves of mafic to ultra-mafic rock intercepted by drilling and observed in the drift, no major units was discovered. The ultra-mafic basement theory may be transferred to a lower level. The geophysics interpretations plan the anomaly around 500m deep. This may be explained by the vertical distribution of the barium. From the surface and down to 200m, the barium is completely depleted. Assays are returning value under the limit detection. Abruptly, the average barium contain rise above 3%, higher than all the other carbonatite facies of the complex. The phenomenon is also slightly observed in the rock density..

Over all, the 2012 drilling exploration program returned excellent results and a lot of new geological data that will be interpreted in 2013. Each drill hole results are summarised in Table 7 below.

Table 7: Drill hole results summary, 2012 REE exploration campaign.

Item 14. SAMPLING METHOD AND APPROACH

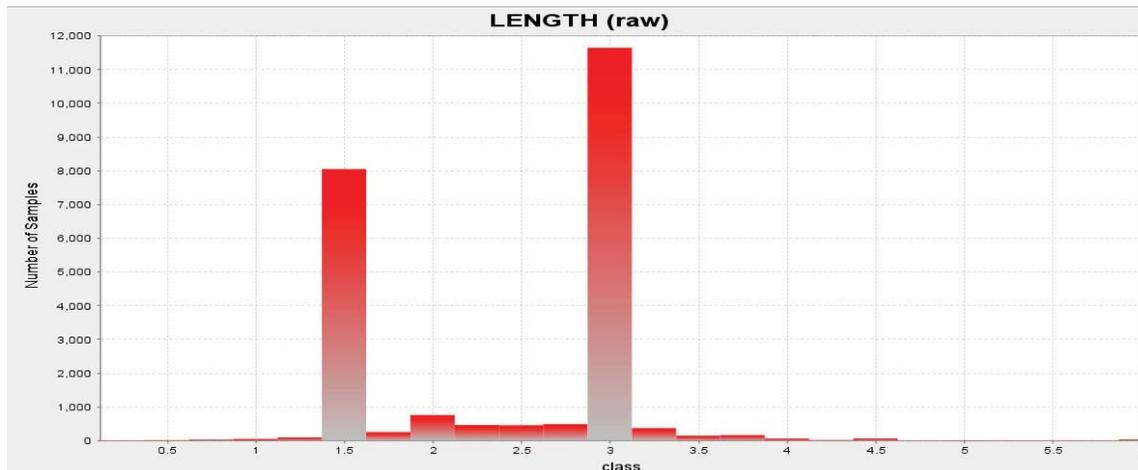

For the exploration purpose, sampling for rare earth elements mineralization is limited to diamond drill core. The complete core logging and core sampling method are described below. Detailed description of the drill core is carried out by experienced and qualified personnel under the supervision of Louis Grenier and Jean-Francois Tremblay, members in good standing of the Ordre des Géologues du Québec.

14.1 CORE LOGGING

The core was described by the IOS geologist using the mine geological facies nomenclature, which is based on Soquem modified facies definition (C1, C2, C3, etc.). Description includes the alteration types, the major structures appearance, a visual quantification of the key minerals abundance (Lanthanides, apatite, etc...) and the others minerals associated the mineralization (magnetite, hematite, chlorite-biotite, pyrite, ankerite, barite, fluorite and sphalerite). Rock Quality Designation (RQD) is systematically measured. All the core boxes are photographed and additional detail photos are taken at a smaller scale when necessary. Since the core is slightly radioactive, a BGO-SPEC SUPER RS-230 device from Radiation Solutions Inc. was used to measure the core radiometry. The radiometric readings are giving in Gy/hr and $\mu\text{Sv} / \text{hr}$.

Following the 2012 P.-J. Lafleur recommendation, the core was sampled on a nominal 3 metres interval (Figure 20). To respect the geological setting, the samples can be shorter or longer. The logger records the sampling intervals (from, to) in the log. A rock code based on the lithology and mineralogy is assigned to each interval. This rock code has an influence in the resource estimation.

Figure 20: Sample length distribution, REE project.

Finally, the hole number, collar coordinates, azimuth, dip, final depth, down-hole survey data, facies description, radiometry core measures and assays (once they have been

received) are incorporated, by the geological mine staff, on the computer log using Gemcom Logger and LabLogger softwares. The geological sections are then published using Gems software from Gemcom for the geological interpretation and the grade visualization.

14.2 CORE SAMPLING

Following the logging procedure described previously, the whole core is sampled based on the intervals identified by the geologist. Core is broken into manageable lengths and cut in half with a diamond blade equipped rock saw. One half is removed from the box and bagged with a serial tag number. The other half is puzzle back into the box with the corresponding analytical tag placed at the beginning of each interval. Core boxes are systematically piled and stored for further needs. Samples bags are shipped in batches (metallic or plastic pails) to IOS warehouse, located at Laterrière (Chicoutimi area, Québec), before shipping to SGS laboratory where the samples are prepared and analyzed.

IOS is a geological service provider independent from IAMGOLD. Samples were prepared by IOS and shipped expeditiously. The quality of their professional services is very high, particularly on issues of sampling and assaying.

It is important to note that several blanks, standard and duplicates samples from IAMGOLD are inserted alternatively every 10 samples (30 metres) approximately. The laboratories also use blanks, standard and duplicates samples of their own to verify their work. The blanks should return no significant REE value within one standard deviation. The standard sample should return their certified REE values within one standard deviation. The duplicates should return the same value as the original sample within a reasonable range of variation. This QA/QC procedure was applies only to the data produced in 2011 and 2012. The details of the QA/QC of historical data (1968 to 1985) are not the same and not entirely documented.

14.2.1 Blank sample

IAMGOLD is using blanks to check the laboratory. The blank is not a certified commercial blank sample. It is coarse material prepared by IOS coming from a quartz vein near Lac St-Jean. It does carry some very low TREE values (119 ppm) as would be the background value of most rocks. The laboratories should return the “standard blank sample” measured low value grade within the range of measured standard deviation over multiple assays or values below detection limits for these blank samples.

Blanks are not like the certified commercial graded samples designed to test the final assay reading instrument. Those standard samples are delivered as fine powder to the laboratory. The blanks are designed to make sure the sample preparation (crushing, splitting and pulverizing) equipment are clean. Therefore, coarse material is sent to the laboratory in larger quantity (2 Kg) in the usual sample bag. It should have as little REE as possible and is the case. If the blanks return much higher values than its measured

grade, it means that the sample preparation facility needs to improve its cleaning procedure. SGS laboratory have been informed of anomalies when they were detected and they applied solutions promptly. The results of using a blank sample in this fashion will inevitably produce results that are more variable than with the certified standard samples. See section 16 for blank results.

14.2.2 Standard

Three different commercial certified standard samples were used alternately:

1. Orea S 101a (low grade),
2. Orea S 146 (medium grade) from Ore Research & Exploration PTY Ltd. and
3. GRE-02 (high grade) from Geostat PTY Ltd.

At the beginning of each hole, a low-grade standard, a high grade standard and a blank were inserted.

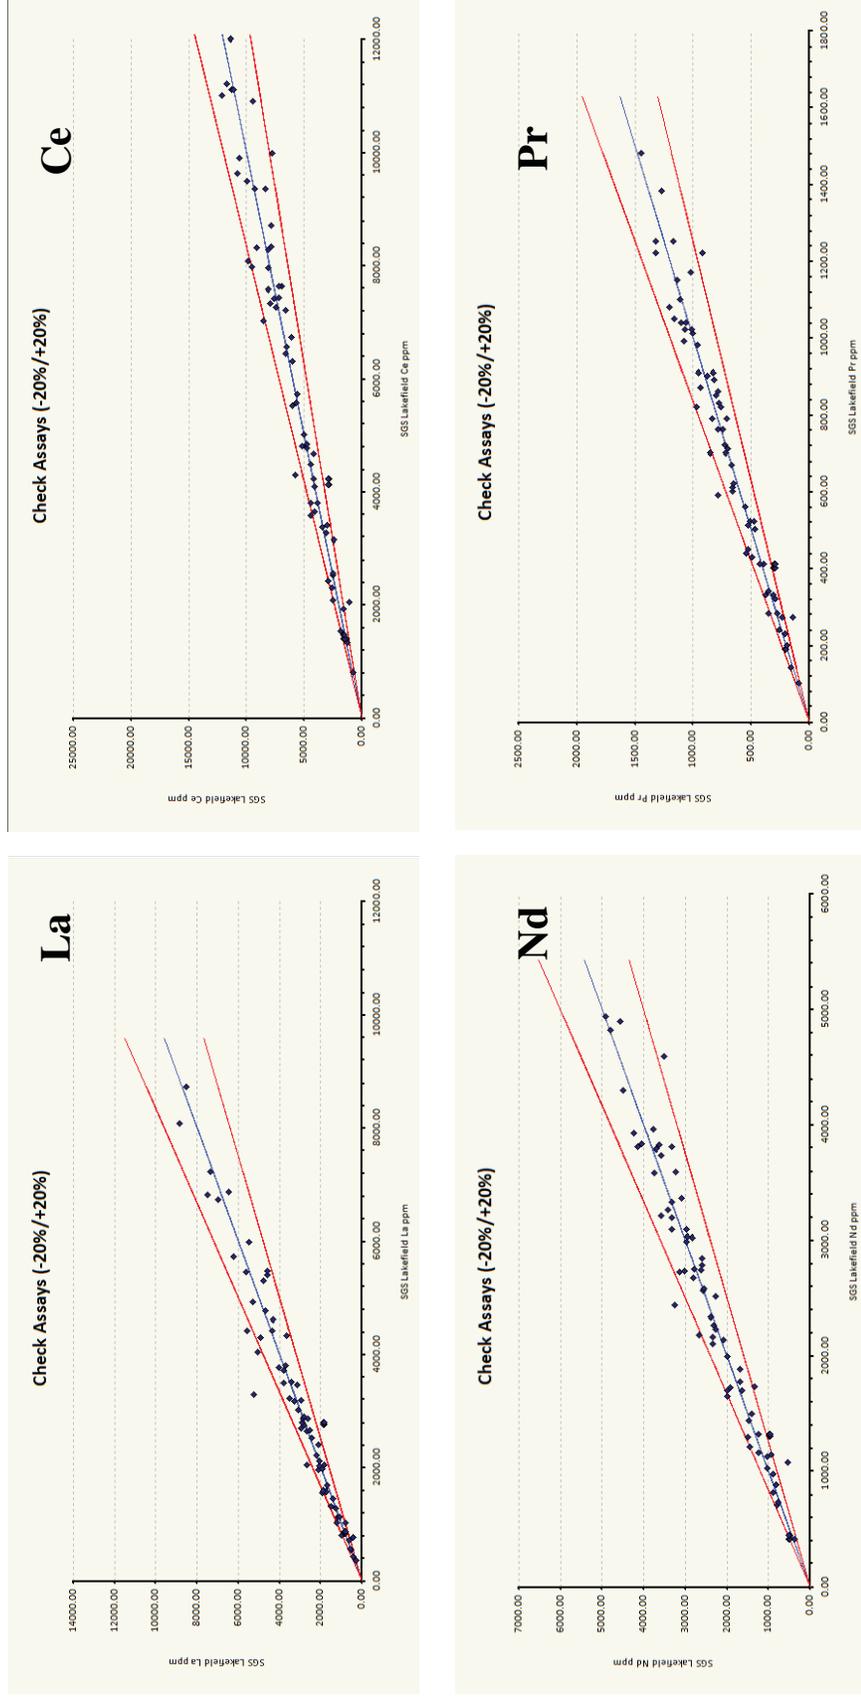

Table 8: Blank and standard samples values (ppm).

STANDARDS	Ce	Dy	Er	Eu	Gd	Ho	La	Lu	Nd	Pr	Sm	Tb	Tm	Yb	Y	U	Th	TREE
Blanks	56	0.3	0.1	0.5	2.0	0.2	29	<0.05	21	6.3	2.6	0.1	<0.05	<0.1	1			119
OREAS 101a	1651	38	23	9.3	54	6.9	897	3.1	475	155	52	7.4	3.4	20	198	482	42	3,394

GRE-02	19308	33	24	167	351	3.7	10449	0.8	8416	2234	866	27	0.7	5.7	69	0.0	0.0	41,886

14.2.3 11.1.2.3 Check sampling (Core Duplicates)

IAMGOLD took 286 valid duplicate samples using split core to test repeatability of results. The laboratories duplicates would be made from crushed or pulverized rock from the split core. Laboratory duplicates are made of smaller portions that are more homogeneous. The results were good. Below are showed the scatter plots of the four principal REE elements.

Figure 21: Core duplicate QA / QC report, REE project 2012.

Item 15. SAMPLE PREPARATION, ANALYSES AND SECURITY

15.1 SAMPLE PREPARATION

Samples were sent to SGS Minerals Services (“SGS”) of Lakefield in Ontario, where all the samples were prepared (crushed, ground, dried) and analyzed. A summary of the sample preparation is following but the detailed SGS analysis and preparation techniques can be consulted on their website (www.sgs.com).

As a routine practice with core, the entire sample is crushed to a nominal minus 10 mesh (2 mm), mechanically split via a riffle splitter in order to divide the sample into a 250 gr sub-sample for analysis and the remainder is stored as a reject. Samples are pulverized to 85% passing 75 micron (200 mesh) or otherwise specified by client. SGS used their own sample preparation control for more accuracy (Table 9).

Table 9: Internal quality control for sample preparation by SGS Ontario.

Crushing Parametres	Frequency	Quality Control Requirement
Prep. Blank	At the start of batch	To Clean Crusher
Prep. Replicates	every 50 samples	75% passing 10 mesh (2mm)
Passing Checks	Every 50 samples	75% passing 10 mesh (2mm)

Regarding samples analysis, SGS laboratory used the following methods:

- **ICM90A**, for 55 elements, by sodium peroxide fusion and a combination of Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES), and Inductively Coupled Plasma Mass Spectrometry (ICP-MS).
- **IMS91B** by sodium peroxide fusion / ICP-MS, for lanthanides surplus upper limit.

15.2 ANALYSIS

15.2.1 ICM90A

Crushed and pulverized rocks are fused by Sodium peroxide in graphite crucibles and dissolved using diluted HNO₃. During digestion the sample is split into 2 and half is given to ICP-OES and the other half is given to ICP-MS. The digested sample solution is analyzed by ICP-OES and ICP-MS. Samples are analyzed against known calibration materials to provide quantitative analysis of the original sample.

The data results fed to the SGS Laboratory Information Management System (SLIM) with secure audit trail are exported online via computer. This method has been fully validated for the range of samples typically analyzed. Method validation includes the use of certified reference materials, replicates and blanks to calculate accuracy, precision, linearity, range, detection limits, and limit of quantification, specificity and measurement uncertainty.

Table 10: Elements analyzed by ICM 90A.

Element	Reporting Limit (ppm)	Upper Limit	Element	Reporting Limit (ppm)	Upper Limit	Element	Reporting Limit (ppm)	Upper limit	Element	Reporting Limit (ppm)	Upper Limit

15.2.2 ICPMS

ICPMS diluted samples to be analyzed on Elan 9000 for 90A samples and Nexion for 91B packages.

Working Calibration solutions and 2nd source calibration check solution was prepared for each analysis run. Re-calibration was done before the analysis of each tray. Additional fusion QC was analyzed every other tray in addition to the QC on each tray.

REE interference corrections were evaluated and corrected.

15.2.3 ICP/OES

Samples are analyzed with a minimum of 10 certified reference materials for the required analyses, all prepared by sodium peroxide fusion. Every 10th sample is prepared and analyzed in duplicate; a blank is prepared every 30 samples and analyzed. Samples are analyzed using a Varian 735ES ICP or a Thermo 6500 ICAP and the method of internal standardization.

For High concentration of REE, the IMS91B analysis technic was used.

Crushed and pulverized rock, samples (0.20 gr) are fused by Sodium peroxide in glassy carbon crucibles in a muffle furnace and dissolved using diluted HNO₃. The fused solution sample is aspirated into the Inductively Coupled Plasma Dynamic Reaction Cell Mass Spectrometre (ICP-DRC-MS). Samples are analyzed against known calibration materials to provide quantitative analysis of the original sample.

The results are exported via computer, on line, data fed to the SGS Laboratory Information Management System (SLIM) with secure audit trail.

Table 11: Reporting limits for REE by IMS91B analysis technic.

Element	Reporting Limits (mg/kg)	Element	Reporting Limit (mg/kg)
Ce	50	Pr	10
Dy	1.0	Sm	10
Er	0.5	Tb	1.0
Eu	1.0	Th	5.0
Gd	5.0	Tm	0.10
Ho	0.10	U	1.0
La	50	Y	5.0
Lu	0.20	Yb	1.0
Nd	50		

Instrument calibration is performed for each batch or work order and calibration checks are analyzed within each analytical run. Quality control materials include method blanks, replicates, duplicates and reference materials and are randomly inserted with the frequency set according to method protocols at -14%.

Quality assurance measures of precision and accuracy are verified statistically using SLIM control charts with set criteria for data acceptance. Data that fails is subject to investigation and repeated as necessary.

15.3 SAMPLE SECURITY

Core samples collected at the drill site are stored in closed wooden core boxes and are delivered to the core-shack facility by the contractor where it is then taken by mine geology personnel. All core logging and sampling takes place in the core-shack. The site is fenced, monitored by close-circuit video cameras and has a security guard posted at all times at the entrance. After the logging and the splitting process, the samples are bagged and packed into plastic or metal pails for shipping. When a hole is completed, IOS Geoservices personnel collect the pails and bring them to their warehouse. The radiometry of each pail is verified to respect the radiometric transportation rules and the shipment is completed. IOS is an independent contractor specialized in the sample management. They follow rigorous methods verified and approved by IAMGOLD-Niobec geological staff. Finally, a carrier transports the sample to SGS facility where they are handled by the laboratory personnel.

Item 16. DATA VERIFICATION

16.1 Verification with laboratory certificates

IAMGOLD-Niobec geological team was receiving electronic Laboratory certificates during the entire program. They were verified and numerically archived on the informatics mine system. SGS also kept a certificate version on their SLIM program. They are available at all time.

In 2012, the Lablogger software from Gems was used to import the certificate into the Gems data base. The data manipulations were restricted and the probability of error decreased. By referring to only one laboratory, SGS, the certificate presentation were standardized and constant all year long.

Lablogger is also used for the QA / QC program.

16.2 QA / QC program

IAMGOLD carried out a QA/QC program with blanks samples, 3 certified REE standards samples (low, medium and high grade) and core duplicates (discussed in Item 14). This is without mentioning the laboratories own check assays and duplicates. Small anomalies were found through the year and were immediately signaled and corrected by SGS. Re-assayed was realised when necessary. A large number of elements, 15 for REE plus numerous associated elements (Ce, Dy, Er, Eu, Gd, Ho, La, Lu, Nd, Pr, Sm, Tb, Tm, Yb, Y, Sc, Nb, U, Th,...), were involved in the QA / QC program but only the four majors REE elements are presented as director line.

16.2.1 Blank sample results and interpretation

The blank sample, which is not a certified commercial blank, is not truly blank. It has a very low average grade of 119 ppm TREE (Table 8) and a relatively high coefficient of variation. The blanks were used 331 times (Table 11) to check the SGS laboratory samples preparation protocol. The TREE averaged valued is 179 ppm and varied from 107 ppm to 334 ppm during the year (Table 12). The coefficient of variation seems to increase with the volume of samples processed in a month. However the average TREE value can reach almost twice the value of the original “blank” sample, those values still very low and near the TREE background limit. Looking at the lanthanum values (Figure 22 and Table 12), the highest level of contamination noticed is 0.06% La (600 ppm). Even if a correction measures was taken in this case, the 0.06% La contamination is very low compared to the 0.4% La mean value for all 2012 samples.

The outliers limits were placed very low for all REEs. In Table 12, the cerium had an all year bad performance with 27% of the sample being above the 100 ppm Ce imposed limit. Once again, even the highest level of Ce contamination (near 1200ppm) is considered marginal compared to the Ce high average value returned in the REE zone. The high variability of the blank samples was not considered problematic for the data base validity.

16.2.2 OREAS 101a results and interpretation

The Oreas 101a was used to verify the REE low grade values accuracy. It is a certified standard provided by an external laboratory. Its average value, 3,394 ppm TREE, is detailed in Table 8. During 2012, the Oreas 101a was systematically sent at the beginning of each batch (each hole) to test the instruments calibration and after inserted randomly with the others standard to validate the accuracy of the analysis.

The Oreas 101a returned an excellent 2012 QA / QC performance (Figure 23). Two isolated certificates needed more supervision and interpretation. In those cases, on the same certificate the other standard and the blank performance were evaluated. Overall, 103 Oreas 101a standards were analyzed and the percentage of outliers reported is very low. The worst performance is coming from the yttrium element. The yttrium is excluded of the total rare earth element content and it was analyzed for the geochemical knowledge of the REE zone and does not influence the resource estimation.

The 2012 average value of each element is generally under the certified average value (Table 13) which means a probable under evaluation of the REE content on the rare low grading assays.

Based on the previous observations, the REE low grading samples were controlled and their data are validated for the purpose of this 43-101 report.

16.2.3 OREAS 146 results and interpretation

The Oreas 146 was used to verify the medium grade REE values accuracy. This certified standard is provided by an external laboratory and the average value of 13,951 ppm TREE is detailed in Table 8. During the 2012 drilling program, the Oreas 146 was inserted randomly with the others standard to validate the accuracy of the analysis.

The Oreas 146 returned an excellent QA / QC performance during all year long (Figure 24). No assays returned values over or under twice the standard deviation limits for the main REE elements. Only the lutetium and the yttrium have shown outlier's values. For both elements, it was judged as isolated cases and not enough significant to alter the data base quality.

Better QA / QC statistics cannot be hoped for a standard. The year average value of each element is almost the same as the certified average value (Table 14) and the coefficient of variation is very low. The Oreas 146 confirmed the laboratory expertise and increased the confidence level of the data base, especially for the medium grading assays.

Figure 23: OREAS 101a QA / QC report, REE project 2012.

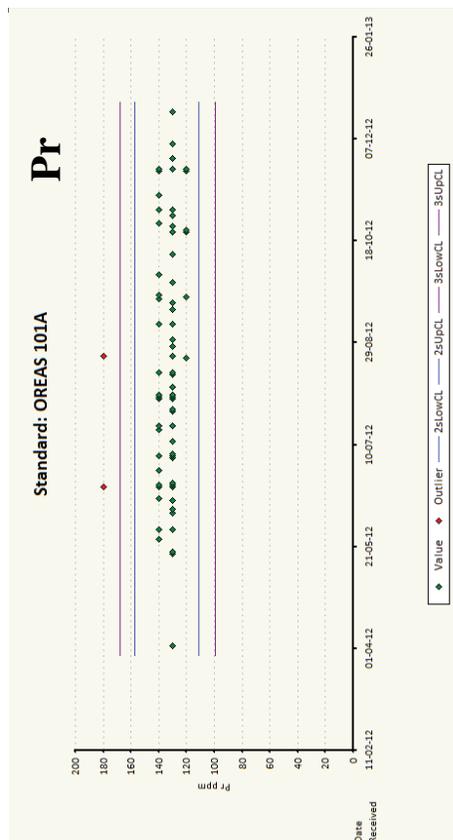

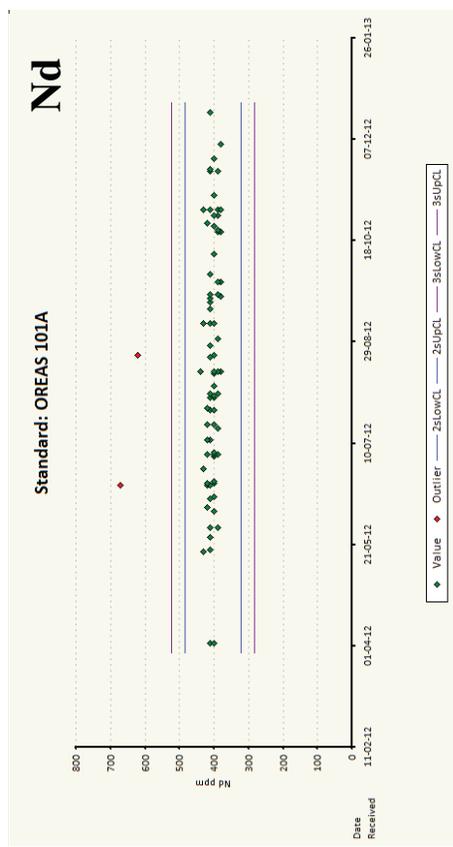

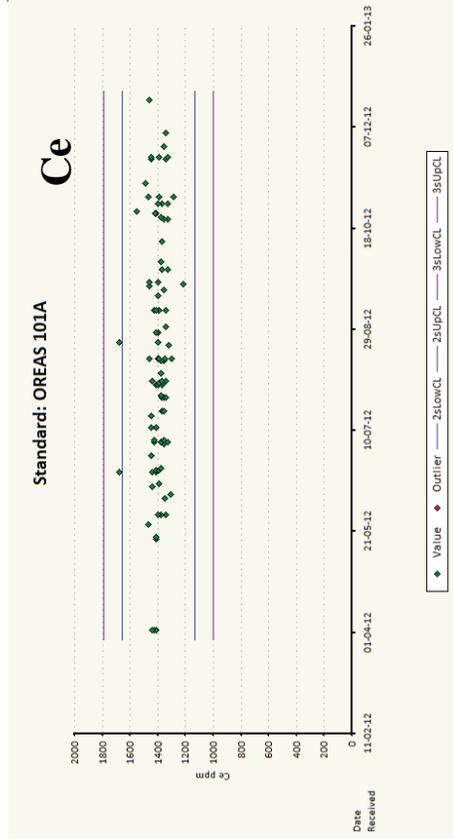

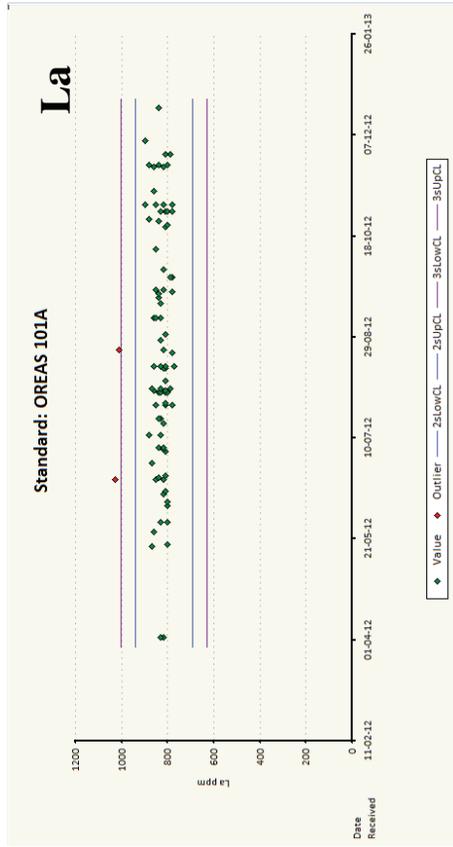

Table 13: Summary of the OREAS 101a QA / QC results, REE project 2012.

16.2.4 GRE 02 results and interpretation

The GRE 02 was used to verify the REE high grade values accuracy. It is a certified standard is provided by an external laboratory and the average value of 41,886ppm TREE is detailed in Table 8. During 2012, the GRE 02 was sent systematically at the beginning of each batch (each hole) to test the instruments calibration and inserted randomly with the others standard to validate the accuracy of the analysis.

The GRE 02 returned a good QA / QC performance during all year long (Figure 25) with a more wide-ranging tendency in the last quarter. The high variation on the low REEs values, especially in the heavy rare earth element range, for a high grade standard like the GRE 02 is considered normal.

Overall, 119 GRE 02 standards were analyzed. The number of outliers for the lanthanum is elevated but the year total average values are similar to the average certified value (Table 15). The coefficient of variation was higher compared to the certified value. On the other hand, the cerium performed better. The all year average value of dysprosium is inferior compared to the certified value. The large amount of the under limit outliers suggest a probable global under estimation of the dysprosium resource for the high grade zone.

Knowing the complexity of analyzing 15 elements with contrasting proportion, the laboratory results for the high grade values are judged acceptable for the resource estimation.

16.3 12.4 Historical Data Verification

The geological data generated after the 1968 discovery up to 1978 included some 546 samples tested for REE over 2,444 metres inside and outside the REE Zone. Most of the assays done on a regular basis were reported on the “paper” (now in PDF) logs for La₂O₃. The few of those drill holes inside the REE Zone are either surrounded by new data, therefore of no importance, or a good temporary support where new data is in progress. The older historical data identified the presence of REE but this data is shallow compared with more recent data (1985, 2011 and 2012).

The data from the surface drill holes 85-01, 85-02 and 85-03 were compared to the data produced by IAMGOLD in 2011. The quality of the data is better today. The 2012 drilling program made the older data least insignificant in number.

At this stage of the REE project exploration, the older historical data is useless. The mineral resource was estimated without this old data.

Figure 25: GRE 02 QA / QC report, REE project 2012.

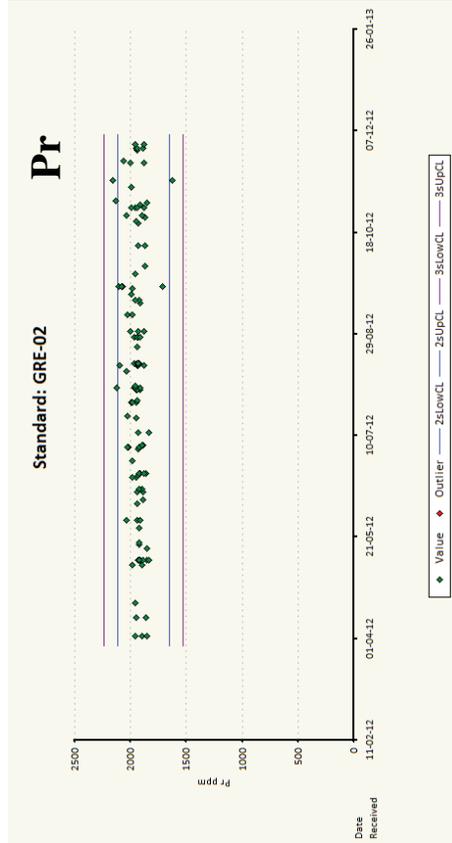

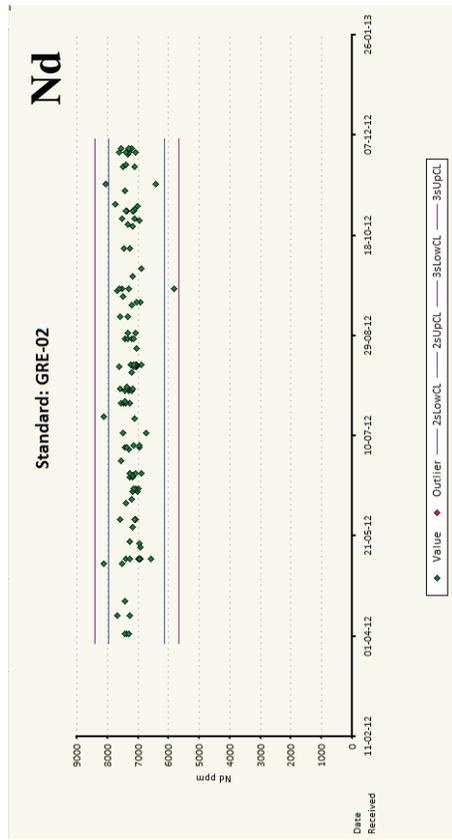

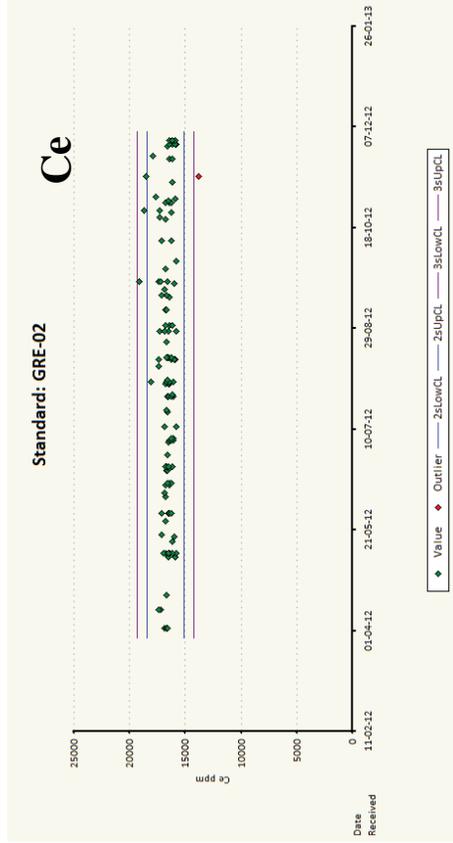

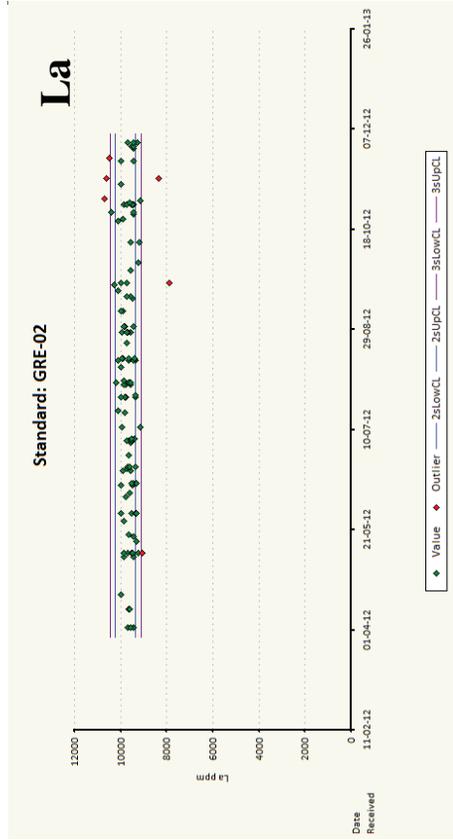

Table 15: Summary of the GRE-02 QA / QC results.

Item 17. ADJACENT PROPERTIES

The recent growing interest for Niobium and REE minerals has generated interest in the general area of the Niobec mine.

At the end of February 2010 DIOS Exploration published the discovery of a satellite carbonatite seven (7) km south of Niobec Mine, the Shipshaw discovery. This prompted the need to review the global setting of the Niobec alkaline and carbonatite complex at the regional scale and evaluate the presence of potential satellite deposits.

The results obtained by DIOS to date in the Shipshaw carbonatite are only anomalous in terms of Nb and REE but this could lead to higher grade or to different styles of mineralization associated to this new carbonatite. An Offer from IAMGOLD to participate in a private Placement of CDN\$1.2 M in DIOS Exploration and to enter in an Exploration Option to Joint Venture on the Shipshaw project was accepted and signed by DIOS on January 13th 2011.

On the closing of the private placement IAMGOLD was granted an exclusive option (the "Option") to enter into an Option and Joint Venture Agreement to earn sixty percent (60%) of DIOS's interest in the Shipshaw Project, Saguenay area, Quebec, within two (2) years of the private placement in DIOS, which Option may not be exercised until the earliest of the time taken by DIOS to spend 80% of the placement on the Shipshaw Carbonatite program (under DIOS' management), or of a period of one year after IAMGOLD has subscribed to the initial private placement. No less than 80% of the placement would be committed to DIOS' Shipshaw Carbonatite program, and any surrounding claims. This has given to IAMGOLD 8.95 % of the then issued and outstanding Common Shares of DIOS after the closing of the placement.

DIOS Exploration is planning various field surveys to execute in the coming months and is currently executing a drilling exploration campaign on their main carbonatite discovery. Several prospective areas staked by DIOS and interpreted from government regional geophysical surveys will be also explored in the current year program.

IAMGOLD-Niobec is following the DIOS exploration results to evaluate the potential of the area for their economic activities.

Item 18. MINERAL PROCESSING AND METALLURGICAL TESTING

Preliminary metallurgical testwork was initiated. Four metallurgical drill holes were executed in March 2011 to provide the metallurgical samples. Samples from two drill holes were combined to make a master composite to begin the metallurgical testwork. In July 2012, all the rejects coming from the 2011 drilling campaign was assembled and sent to a laboratory for a pilot test. In 2012, an exploration drift was developed in the core of the REE

zone, about 300m below surface equivalent to mine level 1150, giving and all year round accessibility. About 3,500 tonnes of bulk material was also stocked underground for future study. Testwork still ongoing and the sections below are based on the 2011 evaluation.

18.1 Mineralogy

Mineralogy (QEMSCAM) has been done on three historical drill hole core samples and two additional on two selected new core samples from 2011 drill holes. The objectives of those mineralogy tests were to identify the major REO minerals, the grain size and form (shape and other physical properties). The major REO identified are Bastnaesite and Monazite in fine cluster assemblage.

Additional mineralogy (QEMSCAM) will be performed on new drillholes to try to do a mapping of the REO minerals to confirm their types and the particle size variability inside the deposit.

18.2 Metallurgical testwork

Metallurgical testwork are ongoing on the cumulate material. Different physical separation methods are investigated including gravity, magnetic, flotation and attrition scrubbing. Preliminary testwork showed results in the range of 58% to 70% REO recovery in a 25% to 40% mass pull respectively. Flotation as per other methodologies continues to improve concentration ratio. Preliminary pre leach tests showed a mass reduction in the range of 80% with the majority of the REO reporting to solid. Additional pre leach test are ongoing as well as REO extraction leach tests.

An average recovery of TREO of 53.5% was assumed for the estimate of the mineral resources.

Item 19. MINERAL RESOURCE AND MINERAL RESERVE ESTIMATES

19.1 Presentation of the REE Zone Mineral Resources Estimates

The REE resource corresponds to an enriched zone of light REEs (“LREE”) which is characteristic of the annular carbonatite type. LREEs comprise 98% of the Total REEs (“TREE”) weight, with the remaining 1.9% of heavy REEs (“HREE”) that could potentially add significant economic value. As indicated in the tables below, the REE zone contains a total Indicated Resources of 531.4 Million tonnes at a grade of 1.64% (8.7 billion kilograms contained) Total Rare Earth Oxides (TREO) and a total Inferred Resources of 527.2 Million tonnes at a grade of 1.83% (9.7 billion kilograms contained) TREO, to a depth of approximately 700 metres.

The estimated resource is enclosed within the core of the carbonatite complex. In 2012, the near surface “footprint” of the mineralization has been confirmed in all directions. Given the homogeneity of the grade values in the block model, it is difficult to outline a low and a high grade zones inside the REE resources. Three holes extended well below the resource model,

and reach a maximum length of 1,337 metres. The two deepest holes demonstrated that the REE zone persists uninterrupted at depth and show comparable or higher grades to other intercepts in the resource model. Based on the low variability and all the preceding information, the mineral resources have been classified by level. The indicated resources are from sub-surface to level 9650 (350m depth) and the inferred resources are from levels 9650 to 9300 (700m depth).

All assay results are reported in Total Rare Earth Element Oxides (“TREO”). The main rare earth elements found are LREEs: Cerium (Ce), Lanthanum (La), Neodymium (Nd), Praseodymium (Pr) and Samarium (Sm), and HREEs: Gadolinium (Gd), Europium (Eu), Dysprosium (Dy) and Terbium (Tb).

Table 16: REE mineral resources by grade groups.

GRADEGROUP % TREO ³	Indicated resources			Inferred resources

NOTES:

- Results are presented in situ, unconfined and undiluted
- Resource modeling used 15,973 samples from the 2011 and 2012 drilling program with 54 elements assayed (with re-assays for high grade samples).

19.1.1 Methodology

19.1.1.1 Software

The Gems LabLogger and Logger software application from Gemcom Software International Inc. were used for core logging, database management, modeling the geology, analyzing the data, to perform the grade interpolations, to create and manage the block model as well as report the mineral resources. The software was used by Louis Grenier and supervised by Réjean Sirois, the qualified person for the resource evaluation according to the NI 43-101.

19.1.1.2 Data

The systematic drilling program of 2011 and 2012, confirmed the results found in the historical drill holes. The question was raised as to whether the historical data should be used in the mineral resource estimation of 2012. Every project goes through the same process of discovery and evaluation from sparse data to detailed data. Each activity from exploration through development and production has different goals and method of investigation.

Between 1968 and 1985, the carbonatite hosting the REE Zone was discovered and studied using various means, including drilling, airborne and ground geophysics, mapping, bulk sampling, petrographic and mineralogy studies, etc. Some 22 shallow surface drill holes were assayed for REE, some sporadically (1968 to 1978), some systematically (1985) and 18 drill holes reported an REE Zone intersect. The original hand written drill logs (*in PDF*) reported values for La₂O₃ only (*to represent the REE group*) in the first 15 drill holes (1968 to 1978). The 3 drill holes from 1985 report 22 assays, including the major REE. All available data were captured into Gems database.

All historical drill holes compared favorably to the 2011 and 2012 drilling results. Most of this data, especially from the period of 1968 to 1978 does not have the QA/QC support to comply with the NI 43-101 standards but there is no evidence that it would not comply with it. The historical data deemed to match the geology and the new grade data available. In fact, it made little difference whether it was used or not. It made no difference in the grade as the old data is completely surrounded by new data. Since new data has been acquired in 2012, the historical data (1968 to 1985) were put aside to favor a more uniform quality of data. The following table summarizes the database tables and fields used in the resources estimation at the 31st of December.

Table 18: Statistics summary of the original assay intervals used in the 2012 resource estimation.

Samples statistics	2012-12-31
Number of samples	15,973
Average length (m)	2.21
Minimum (ppm TREO)	89.82
Maximum (ppm TREO)	123403.10
Mean (ppm TREO)	17106.96
Median (ppm TREO)	16611.10
Variance	91535769.77
Standard deviation	9567.43
Coefficient of variation	0.56

19.1.1.3 Composites

Compositing is a set of techniques to split, group and regroup existing samples to make them “even” and ready for the interpolation process on a regular 3D grid, the block model. Drilling and sampling is not even. It is done on line, sections and levels where the access is available to take the samples most efficiently. Drilling is also a process to discover the shape of a mineral resources and increase the detail as the exploration program is going on. For the interpolation process of assigning a grade value to each block, the blocks and the samples must have a matching rock type.

For the estimation of the REE Zone mineral resources in 2011, several sets of data were tested against several geological models (Lafleur, P.-J., 2012). Those are:

- Up to 9,398 original assay data from the ICP table in variable length but mostly 1.5m;
- 3,126 5m composites including all drill holes intersecting the REE Zone;
- 2,871 5m composites for 1985 to 2011 drill holes exclusively;
- 1,672 10m composites including all drill holes intersecting the REE Zone.

Because the drill hole samples in the REE Zone vary in length, it was deemed valid to group samples in equal length. Composites of 10 metres appear to be a good choice according to the geology, the sampling statistics and the variography. The final length of 5 metres was retained after looking at different block models section and plan views. Composites of larger size smooth the data. Five metres equal length composites appeared to be a better choice than the 10 metres composites to preserve a certain level of details in the grade model. No top grade capping value was used before or after compositing. This can be done dynamically during interpolation in Gems.

The 2011 composites parameters were applied to the data set used for the 2012 block model. The data set is formed of 7,110 of 5 metres composites including 2011 and 2012 drill holes intersecting the REE zone (Table 15). The 2011 samples were principally of 1.5 to 2 metres long and the 2012 samples were uniformly set at 3 metres long. An equal length composite of 5 metres was judged appropriate to keep a detailed grade distribution in the model.

Table 19: Composites statistics summary used in 2012 resource estimation.

5 m Composites statistics	2012-12-31
Number of samples	7,110
Minimum (% TREO)	0.02
Maximum (% TREO)	8.17
Mean (% TREO)	1.69
Median (% TREO)	1.72
Variance	0.71
Standard deviation	0.84
Coefficient of variation	0.50

19.1.1.4 Variography

The variography is used for the 2012 rare earth elements resources estimation. It was made for the reported total rare earth oxide (TREO). A standard approach was used to generate and model the variography. The following steps were followed:

- Orientation and the dips examination of the solids representing the REE zone to determine the continuity axes.
- Generated and model the down hole correlogram, which determine the nugget effect (closed space variability).

- Calculate and model the major, semi-major and minor axes of continuity.

The anisotropy direction was determined using the regressions rules in “SAGE” software. The variogram was modeled with a nugget effect and two structures representing the larger scale spatial variability of the datasets. The modeled correlogram is summarized in Table 20. The rotation angles use the Gemcom convention around the ZYZ axes based on the orientation of the block model.

The set of rules would be the same for all REO as for TREO except the limits on grade for the Top Cut Value and the Cut-Over High Grade Value would have to be adjusted accordingly.

Table 20: Variography statistics

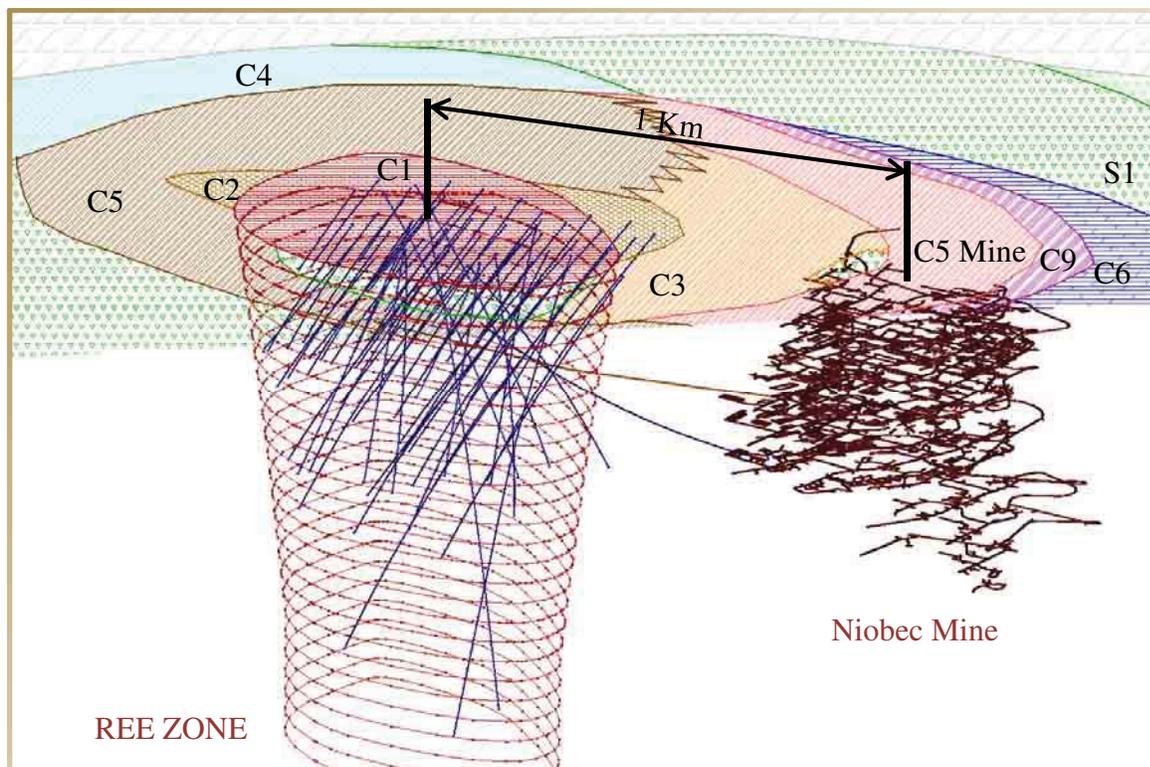

Element	Nugget effect	Ranges (m)		Rotation (°)		
		1 st Structure	2 nd Structure	Z	X	Z
TREO (%)	0.422	X:50 Y:150 Z:360 Sill:0.431	X:750 Y:360 Z:700 Sill:0.147	0	0	0

19.1.2 Domain and Volume

The REE Zone mineral resources model is limited to the core of the Saint-Honoré carbonatite complex. The C1 rock type is (the REEs mineralized carbonatite) containing the majority of the mineralization but a surrounding crown, called the transition zone, included the low grade values. The transition zone is formed of mineralized C1 injected in the C2 (massive carbonatite) and the S1 (syenite). The geological model outlying the REE host rock was drawn in 2011. A vertical projection was drawn from the surface compilation map (Figure 5) using a 70° dip cone shape truncated first at 1000m depth in 2011 and extend at 1400m depth in 2012 (Figure 26). The volume is adjusted to the drill hole rock type description and assay values to obtain a 3D cone shape confining the grade interpolation process.

The geological model will be reviewed in 2013 with all the new data collected by drilling in 2012. The core zone and the transition zone will be separated for a better definition of the resource. However the geological model is not up to date, the 2011 model is judged enough close to the reality to use it for generating a valid resource interpolation.

Figure 26: 3D Shape of REE Zone (left) and Niobec mine (right)

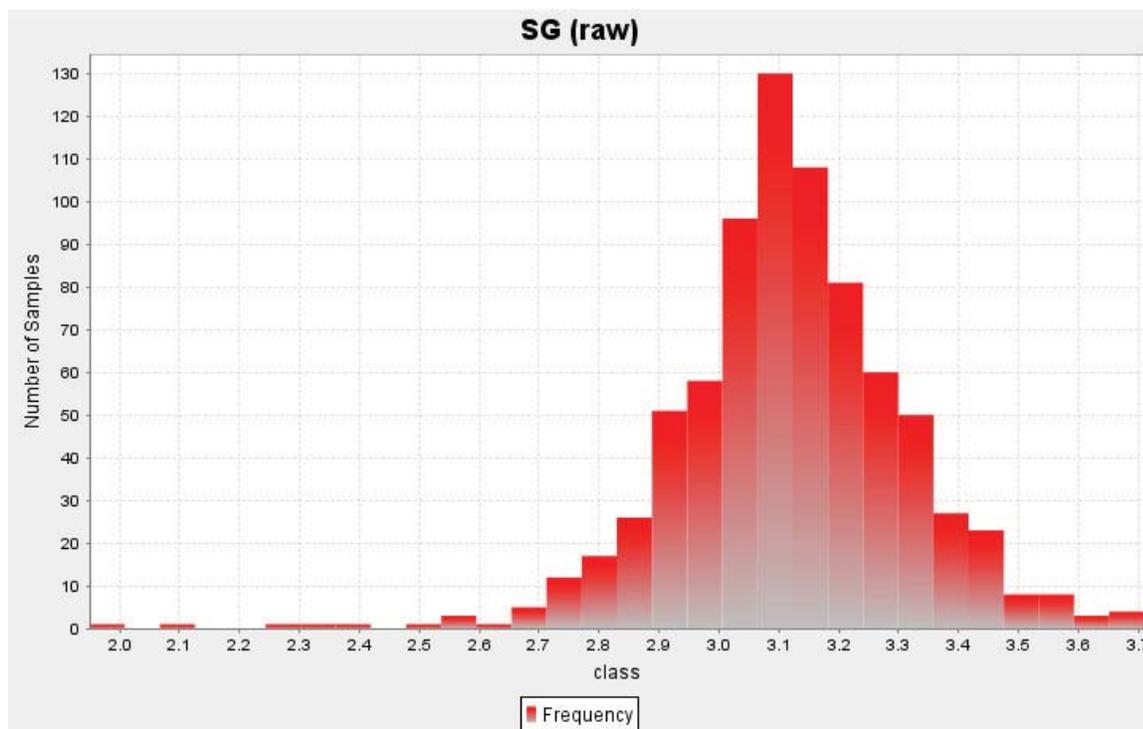

19.1.3 Specific Gravity (SG)

A systematic specific gravity measurement was realized during the 2012 drilling campaign. The density test was realized by Niobec staff using the water immersion technique on representative core sample of ± 15 cm long. Each corresponding 3 metres long sample sent for analysis was also analyzed by SGS using an air pycnometer on pulverized samples. Both technic returned similar SG values, the SGS values were choose to be including in the database. The density is now available not only for every different geological interval described but also on a 30 metres frequency along each hole. Coupled with the 2011 values, 777 density measurements, mainly located in the C1, were used for the interpolation (Figure 27).

Even if the new sample average density is 3.11 t/m^3 , the 2011 density value of 2.86 t/m^3 was used has default value for the blocks with insufficient data during the interpolation process.

Figure 27: Histogram of 777 Density Measures.

19.1.4 Block Model

The REE2012 block model was built within the GD_TR_2012 database, Gems 6.3.1 software. The estimated mineral resources have been modeled using a 10-metre cubic block model and grades were estimated using Ordinary Kriging (OK) over 5 metres equal length composites. The block model parameters are summarized in Table 21.

Table 21: REE zone block model parameters (Exploration metres).

	Easting	Northing	Elevation
Minimum coordinates	2,000	5,00	8,600
Maximum coordinates	3,200	6,400	10,100
Block size	10	10	10
Number of blocks	120	140	150
Rotation	0	0	0
References: Exploration Grid; Unit: metres			

The domain coding (rock type model) was based on the various wireframe constraints (Table 22). Each block was given a rock type attribute following a rule of precedence. All blocks were first selected and given the rock type 0 (air). Then, all blocks between the topographic surface and the overburden surface were given the rock type 1 (overburden). The rock type 2 (Trenton limestone) was attributed to all blocks between the overburden surface and the Trenton limestone surface. Finally, the Saint-Honoré carbonatite complex was divided in

domain based on the vertical interpolation of the compilation surface map (Figure 5). All blocs under the Trenton limestone surface were given the rock type number associated to their domain (Table 22).

Table 22: Block model coding.

Type	Name	Description	Block Model Code
Topography	Topo	Topography based on header altitude.	0 "air" (above the surface)
Surface	OB	Overburden	1 (above the surface)
Surface	Trenton	Base of the Trenton limestone	2 (above the surface)
Geology	C1	REE mineralized dolomite	10
Geology	C2	Massive dolomite	20
Geology	C3	Nb mineralized, foliated dolomite or calcitite	30
Geology	C5	Nb mineralized, coarse grained dolomite	50
Geology	C6	Pyroxene bearing calcitite	60
Geology	S1	Syenite	110

Within the block model project, a series of models were incorporated for recording the different attributes assigned and calculated in the block model development. These attributes are listed in Table 23 below.

Table 23: Block model attributes.

Attribute name	Description and Content	Unit	Update or creation procedure	Default value	Mapping	Data type
Rock type	Geologic code 0=Air 1=Overburden 2=Trenton limestone 10=C1 20=C2 30=C3 50=C5 60=C6 110=S1	-	Limited by surfaces 50% over topo 50% over OB 99% over Trenton C1 domain C2 domain C3 domain C5 domain C6 domain S1 domain	0	Rock type	Integer
Density	Density value from actual data Air=0 Overburden=1.8 Trenton=2.78 Carbonatite=2.86	t/m ³	Updated from the rock code profile.	2.86	Density	Single
TREO_PCT	TREO grade	%	Interpolation, ordinary kriging	0	TREO	Single
CAT	Resource classification 1=Measured 2=Indicated 3=Inferred 4=Mineral inventory	-	Based on the search ellipse and limited by depth with the drill hole mesh coverage.	0	CAT	Integer

19.1.5 Grade Interpolation

Grade estimation was done using an ordinary kriging method in Gems 6.3.1 software. The method was applied with a numerical digitation of the 3 x 3 x 3 blocks. The interpolation threatened a data base of 5 metres equal length composites obtained from the original assays. The ordinary kriging was completed using a sample search approach as summarized below:

- The first interpolation for each block is calculated with a minimum of 6 and a maximum of 12 composites within the search ellipse. The ellipse dimension is limited to 100m x 100m x 100m (Figure 28). There is no maximum number of samples per drill hole.
- Then, a second interpolation is calculated with a minimum of 2 and a maximum of 12 composites within the search ellipse. The ellipse is less restrictive and has a dimension of 150m x 150m x 150m (Figure 29). Once again, there is no maximum number of samples per drill hole.

A top value capping is used in both cases. A value of 10% TREO was used for this purpose. In addition, Gems allow reducing the range of influence of high grade values. A high grade cut-over of 5% TREO was used. The high grade values are used in the interpolation up to 10% with a range half of the rest of the data. This way, if a cluster of high grade value is intersected, Gems will generate a high grade zone in the block model. Otherwise, an isolated high grade value will be discounted more heavily.

The TREO value was the only one interpolated in 2012. It perfectly reflects the global distribution and the economic value of the REE zone. Each 14 rare earth elements could be interpolated individually for comparison or other specific purpose. These elements could be estimated using the same methodology as described for TREO.

Table 24 shows the complete search parameters, Appendix 1 the main section view and plan view of the 2012 block model TREO grade interpolation.

Table 24: Interpolation rules

19.1.6 Classification

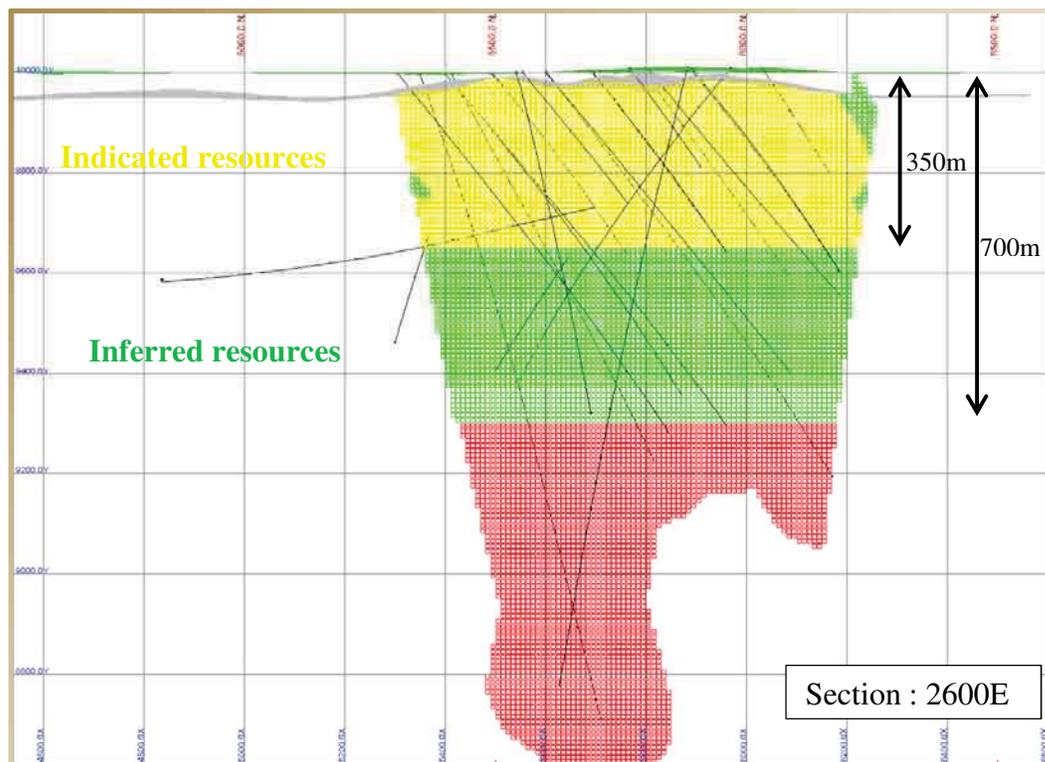

The Mineral Resources estimated for the REE deposit were classified according to the “CIM Definition Standards for Mineral Resources and Reserves” (December 11, 2005).

IAMGOLD mandated the consulting firm G Mining Services to support the Niobec geology team in achieving and validating the 2012 resources calculation. These resources are classified according to the drill hole coverage and the REE mineralization continuity interpreted by the qualified person.

The new drilling grid, 100m x 100m down to 350m below surface, define the rare earth elements hosting rock (C1). All limit, north, east, west and south, were intersected and the geometry of the ore body is trace on sub surface. From 350m to 700m below surface, is spaced by a drilling grid of 100m x 200m. The cylinder shape of the mineralized C1 can be, without confusion, extended at depth. With only a few holes going down to ± 1200 metres, the REE zone is judged continuous in grade and still open at depth.

Base on the actual knowledge of the REE zone, the indicate resource correspond to the first interpolation rules and are limited to the 9650 level (350m below surface) (Figure 30). From 350m the drill definition decreased and the resources were called inferred. Even if the block model was extended at depth, the resource calculations were limited to 700 metres below surface. At this stage, no reserves were defined for the REE zone.

Figure 30: Resource classification, typical section view.

Sections 19.2 to 19.9 are required for advanced project only

19.2 Mineral reserves estimates

No mineral reserves estimates were outline for the REE Zone at this stage.

19.3 Mining methods

No mine plan was drawn for the REE Zone. However, the proximity to the existing IAMGOLD Niobec underground mine makes it an obvious choice as long as the value of the mineral resources is equal or higher than the niobium ore. The value of the REE Zone material has been more valuable than the niobium ore recently with the peak in REE prices but that was not always the case historically. The alternative of mining at surface with an open pit is also attractive given the facts:

- The REE Zone outcrops or is under less than of 30m Trenton limestone and overburden;
- it would be a lower cost operation than underground near the surface; however contemplating a very deep pit is much less attractive;

The REE Zone could be mined from surface and underground at the same time also. But with the actual works made on the Niobec underground feasibility project (based on a Blocks Caving method), an underground mining method should be preferred for this project.

19.4 Recovery methods

Preliminary metallurgical test work results of a REO bulk concentrate shows recoveries between 58% and 70%. Optimization test will continue throughout 2013 and preliminary leach tests as well as extraction leach tests are ongoing. A final recovery of 53.5% of the REE is for the moment assumed.

19.5 Project infrastructure

There is no specific project infrastructure for the REE Zone at the moment. However, IAMGOLD owns Niobec Inc. which operates an underground niobium mine just 1km from the REE Zone with an on-site mill and tailings disposal facilities.

19.6 Market studies and contracts

This section will be addressed when IAMGOLD produces a preliminary economic assessment or scoping study.

19.7 Environmental studies, permitting and social impact

This section will be addressed when IAMGOLD produces a preliminary economic assessment or scoping study.

19.8 Capital and operating costs

This section will be addressed when IAMGOLD produces a preliminary economic assessment or scoping study.

19.9 Economic analysis

This section will be addressed when IAMGOLD produces a preliminary economic assessment or scoping study.

Item 20. OTHER RELEVANT DATA AND INFORMATION

There is no other relevant data or information that will make this technical report more understandable and not misleading.

Item 21. INTERPRETATION AND CONCLUSIONS

21.1 Geological compilation:

The large 2012 drilling program bring new geological information about the REE zone. A complete compilation of the historical data was done in 2011 and not repeated in 2012. The new data was merged into the global data base. In the well-known Saint-Honoré carbonatite complex context, the anterior version of the geological model was judged enough realistic for the purpose of this report. The geological model will be actualised in 2013 by interpreting the high definition magnetic survey and the new drilling information.

The 2012 definition program focused on the carbonatite complex. The REE mineralization is limited to the REE Zone which corresponds to the central core of the carbonatite complex. The main REE minerals are: bastnaesite and synchysite, both disseminated in the ferrocarnatite. It is accompanied with hematitic and /or chloritic alteration in the breccia facies but also find as centimetre scale, reddish coloured clusters in the massive facies. The change of textures, from breccia to massive, are often but the mineralisation contain is homogeneous.

21.2 Drilling

IAMGOLD drilling 2012 campaign (33 holes totalling 23, 851 m) tested the REE zone to a vertical depth of 1,200 m. This drilling campaign, defined the tridimensional shape of the REE zone, detailed the resources model and proved the mineralization continuity down to $\pm 1,200\text{m}$.

It is important to notice that this drilling campaign used a N031° grid orientation (to keep the same orientation as the mine grid) and completed a 100m X 100m grid down to 350m below surface. From 350m to 700m, the drilling grid is spaced to 100m x 200m. This new spacing allowed to transform the 2011 inferred resources into indicated resource and stretched the grade interpolation at depth.

The 2012 drill campaign, drill core handling, logging and sampling protocols were improved and are according to conventional industry standards and conform to generally accept best practices.

21.3 Mineral resources estimation – REE zone

This report include a new resource estimate based on 2012 REE exploration and definition update. The drilling added in 2012 increased the confidence level of the block model interpolation and double the resource estimation compared to last year. The REE resource corresponds to an enriched zone of REEs mineral which is characteristic of this annular carbonatite type.

As shown in Table 25 below, the REE zone contains a **total Indicated Resources of 531.4 Million Tonnes at a grade of 1.64% Total Rare Earth Oxides (TREO) and a total Inferred Resources of 527.2 Million Tonnes at a grade of 1.83% TREO**, to a depth of approximately 700 metres (the surface lies at a reference elevation of 10,000 metres). The exploration drilling confirmed the mineralization continuity below the fixed level of 700m and still open at depth.

Table 25: 2012 REE resources and reserves estimation.

REE (Rare Earth Elements) Project		December 31, 2011			December 31, 2012		
		Tonnes (000)	% TREO	Kg TREO (000)	Tonnes (000)	% TREO	Kg TREO (000)
Iamgold (100%)	Proven reserves						
	Probable reserves						
	Total reserves	0	0.00	-	0	0.00	0
	Measured resources						
	Indicated resources				531,400	1.64	8,730
	Measured and Indicated resources	0	0.00	-	531,400	1.64	8,730
	Inferred resources	466,800	1.65	7,702	527,200	1.83	9,652

Item 22. RECOMMENDATIONS

22.1 Geological compilation and resources modelling.

The new geological information collected during the 2012 drilling program was not totally interpreted. The REE zone contacts were frequently intercepted, especially at depth, and an update of the geological model is needed. In the Saint-Honoré carbonatite complex context, the 2011 geological model (Lafleur, P.J., 2012) contained enough detail to update the TREO resources without any doubt on the reliability of the results. By modeling the transition zone (“low grade zone”) and the REE core zone (“high grade zone”) a grade interpolation could be applied individually to those new geological volumes. The expected results on the resources model will be an increasing of the TREO concentration coupled with a decreasing of the tonnage in the core zone. With cumulative mineral inventory of over 1 billion tonnes, decreasing the tonnage won’t have a negative aspect compared to the benefit of increasing the concentration.

The specific gravity used for the 2012 block model included the 2011 back ground value for the carbonatite of 2.86 t/m³. Basic statistics made over the new available density data base returned an average value for the carbonatite of 3.11 t/m³. This change must be studied. An increasing amount of barite is noted at depth and must necessarily affect the density. A density distribution pattern, within different geological domain or inside one domain, must be integrated to the next geological interpretation and blocks model.

The TREO value is a composite of 14 individual rare earth elements values added together. A proportion relationship between each element was established by P.J. Lafleur. Base on this information only the TREO attribute was calculated for the 2012 block model. The statistic and the variography of each element should be added for validation or comparisons.

22.2 Mineralogical characterisation and metallurgy.

A Mineralogical study is ongoing. The petrographic, the geochemical and the mineralization characterisation of the REE zone at depth, under 500 metres below surface, are the objects of a master project. Preliminary report should be produced to help the geological modeling and metallurgical test works. A synergy between geological improvement and metallurgical testing would be benefit to the REE project.

The hyper spectral technology might help the geological team to build a homogeneous data base to improve the actual geological model. Even if the traditional core logging description seems to work for outlying the core zone, the spectral technology can precisely evaluated the REE mineral concentration and nature especially in the brecciated facies where the granulometry become smaller. It is recommended to test the benefit of the hyper spectral technology by building the library with the entire representative and available core.

22.3 Drilling

Below surface to 700 metres few drill holes crossed the inferred resources bottom line and demonstrated the continuity at depth of the mineralized zone at depth. An increasing of the REE mineral contain is visually observed and reported by the assays. With the actual drilling pattern, the geological property change, in the holes 2012-REE-033 and 2012-REE-034, may be considered local. Local grade variation can be observed in the well define upper level. Tighten the drilling mesh would confirmed the increasing grade with depth hypothesis or at leases confined the high grade zone.

More drilling will be necessary to upgrade resources into reserves. A 50m x 50m drilling mesh pattern could be tested. The underground access could provide an easy all year round access.

Item 24. CERTIFICATE OF QUALIFICATION

CERTIFICATE OF QUALIFICATION

As an author of this report on a mineral property of Niobec inc. (Niobec Mine 100% owned by IAMGOLD CORPORATION) located at 3 400 chemin du Columbiun, St-Honoré de Chicoutimi, Québec, G1V 1L0, I Louis Grenier, do hereby certify that :

1. I reside at 88 4E Chemin Lac Brochet, Saint-David-de-Falardeau, province of Québec, Canada, G0V 1C0
2. I am registered professional geologist, member in good standing of Ordre des Géologues du Québec, (OGQ #800);
3. I graduated from the Université Laval, Quebec city, in 2003 and have a Bachelor's degree in Geology;
4. I have practiced my profession as geologist in, mineral exploration and mineral production over the last 10 years.
5. I have been working for Virginia Mines from 2004 and 2012 as an exploration and project geologist.
6. As a surface exploration geologist since March 2012, I am a full-time employee of Iamgold-Niobec (Iamgold/Niobec, Quebec, Canada) and I own shares of IAMGOLD CORPORATIONS;
7. I have been in charge since 2012 of the drilling campaigns and involved in resources calculation of the Iamgold Rare-Earth project.
8. I am not aware of any new information on events occurring subsequent to February 22nd, 2013 that could have a material effect on the resource estimates presented in this Document.

Prepared in St-Honoré-de-Chicoutimi, this 22nd day of February 2013,

Louis Grenier, géo. (OGQ, #800)
Exploration Geologist
Niobec inc. (IAMGOLD)

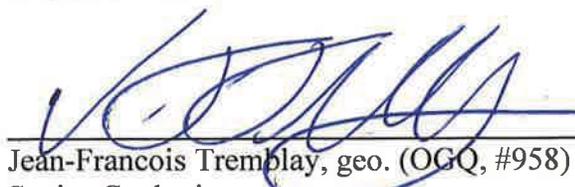

CERTIFICATE OF QUALIFICATION

As an author of this report on a mineral property of Niobec inc. (Niobec Mine 100% owned by IAMGOLD CORPORATION) located at 3 400 chemin du Columbiun, St-Honoré de Chicoutimi, Québec, G1V 1L0, I Jean-Francois Tremblay, do hereby certify that :

1. I reside at 2972, St-Etienne, in city of Jonquière, province of Québec, Canada, G7S 1H6
2. I am registered professional geologist, member in good standing of Ordre des Géologues du Québec, (OGQ #958);
3. I graduated from the Université du Québec à Chicoutimi in 1999 and have a Bachelor's degree in Geology;
4. I have practiced my profession as geologist in, mineral exploration, environment and mineral production over the last 12 years.
5. I have been working for Falconbridge/Xstrata Nickel From 2000 and 2001 and from 2004 to 2009) as a project geologist and production geologist on different Canadian geological environment;
6. As a Senior Geologist since March 2010, I am a full-time employee of Niobec mine (Iamgold/Niobec, Quebec, Canada) and I own shares of IAMGOLD CORPORATIONS;
7. I have been involved in the last tree (3) reserves and resources Estimation for Niobium type mineralization with different mining method.
8. I have been in charge since 2011 of drilling campaigns and involved in resources calculation of the IAMGOLD Rare-Earth project.
9. I am not aware of any new information on events occurring subsequent to February 22nd, 2013 that could have a material effect on the resource estimates presented in this Document.

Prepared in St-Honoré-de-Chicoutimi, this 22nd day of February 2013,

Jean-Francois Tremblay, geo. (OGQ, #958)
Senior Geologist
Niobec inc. (IAMGOLD)

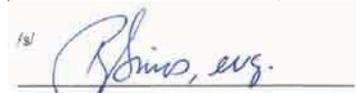

2013/02/22

CERTIFICATE OF QUALIFICATION

I, Réjean Sirois, *Vice President, Geology and Resources*, at G Mining Services Inc., 1950 Blvd Taschereau, D Building, Suite 200, Brossard, Québec J4X 1C2, hereby certify that:

1. I am a registered member of Ordre des Ingénieurs du Québec, # 38754;
2. I am a member of the Prospectors & Developers Association of Canada, # 14892;
3. I graduated from the Université du Québec à Chicoutimi in 1983 and have a Bachelor's degree in Geological Engineering;
4. I have practiced as a geological engineer since my graduation in exploration and mine geology. Over the last 27 years, I have completed numerous resource estimates for gold, silver, base metals and industrial minerals;
5. I have been working for G Mining Services Inc. since September 2012 as Vice President, Geology and Resources. I have worked for Cambior/IAMGOLD for 25 years as senior geologist, chief geologist, geology superintendent, mine manager and as Manager – Mining Geology;
6. I have visited all IAMGOLD's projects and mines and I have a good understanding of their geological environment;
7. Denis Miville-Deschenes (SVP, Project Development) gave me the following mandate:
 - a) Assessment of the various QPs (member of professional association recognized by NI 43-101 and pertinent experience in resource or reserve estimation);
 - b) Assessment of the Mineral Resource & Mineral Reserve "MRMR" from each mine or project as December 31st, 2012;
 - c) Make appropriate validation and checks to insure that the MRMR are in line with the CIM standard definitions for Resource and Reserve reporting and can be reproducible.
 - d) Validate all the process and assumptions used for resource and reserve estimations and reporting.
 - e) Prepare the corporate MRMR statements, the year-end report and sign-off on the IAMGOLD MRMR.
8. At the date of this certificate, to the best of my knowledge, the report entitled: "NI 43-101 Technical report, Surface diamond drilling exploration program for rare earth elements, 2012 NIOBEC MINE PROPERTY", dated March 18th, 2013 contains all the necessary information that is required to be disclosed to make the reports not misleading.
9. I am a "Qualified Person" according to the NI 43-101 definition;
10. I am independent of IAMGOLD Corporation as set out in Section 1.5 of National Instrument 43-101.
11. I am a full-time employee of G Mining Services Inc. and do not own shares of IAMGOLD CORPORATION.

Effective on this 18th Day of March 2013

Réjean Sirois, Ing.
Vice President, Geology and Resources
G Mining Services Inc.

**Item 25. ADDITIONAL REQUIREMENT FOR TECHNICAL REPORTS ON DEVELOPMENT PROPERTIES
AND PRODUCTION PROPERTIES**

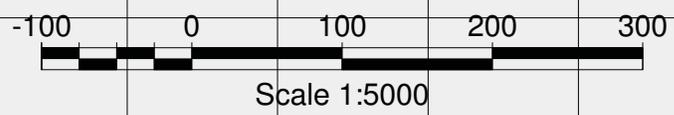

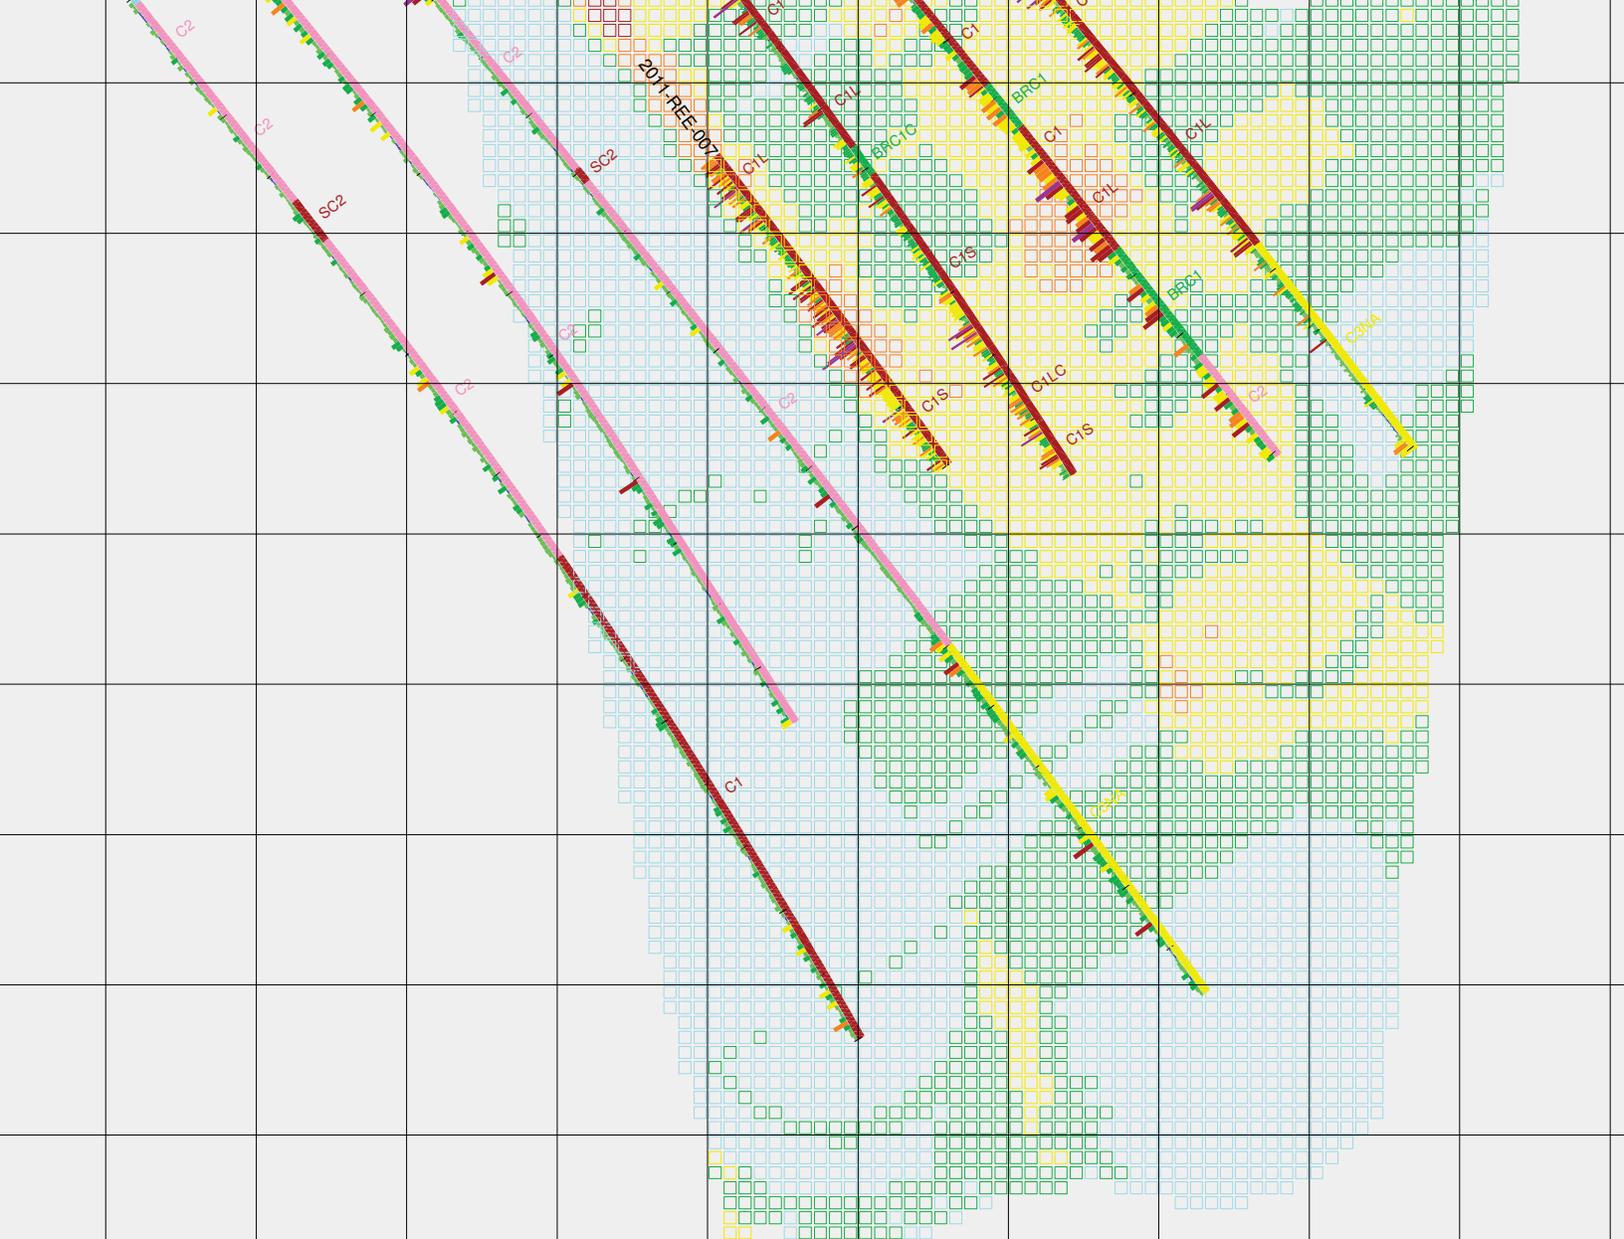

There is no additional requirement for this technical reports.

Item 26. ILLUSTRATIONS

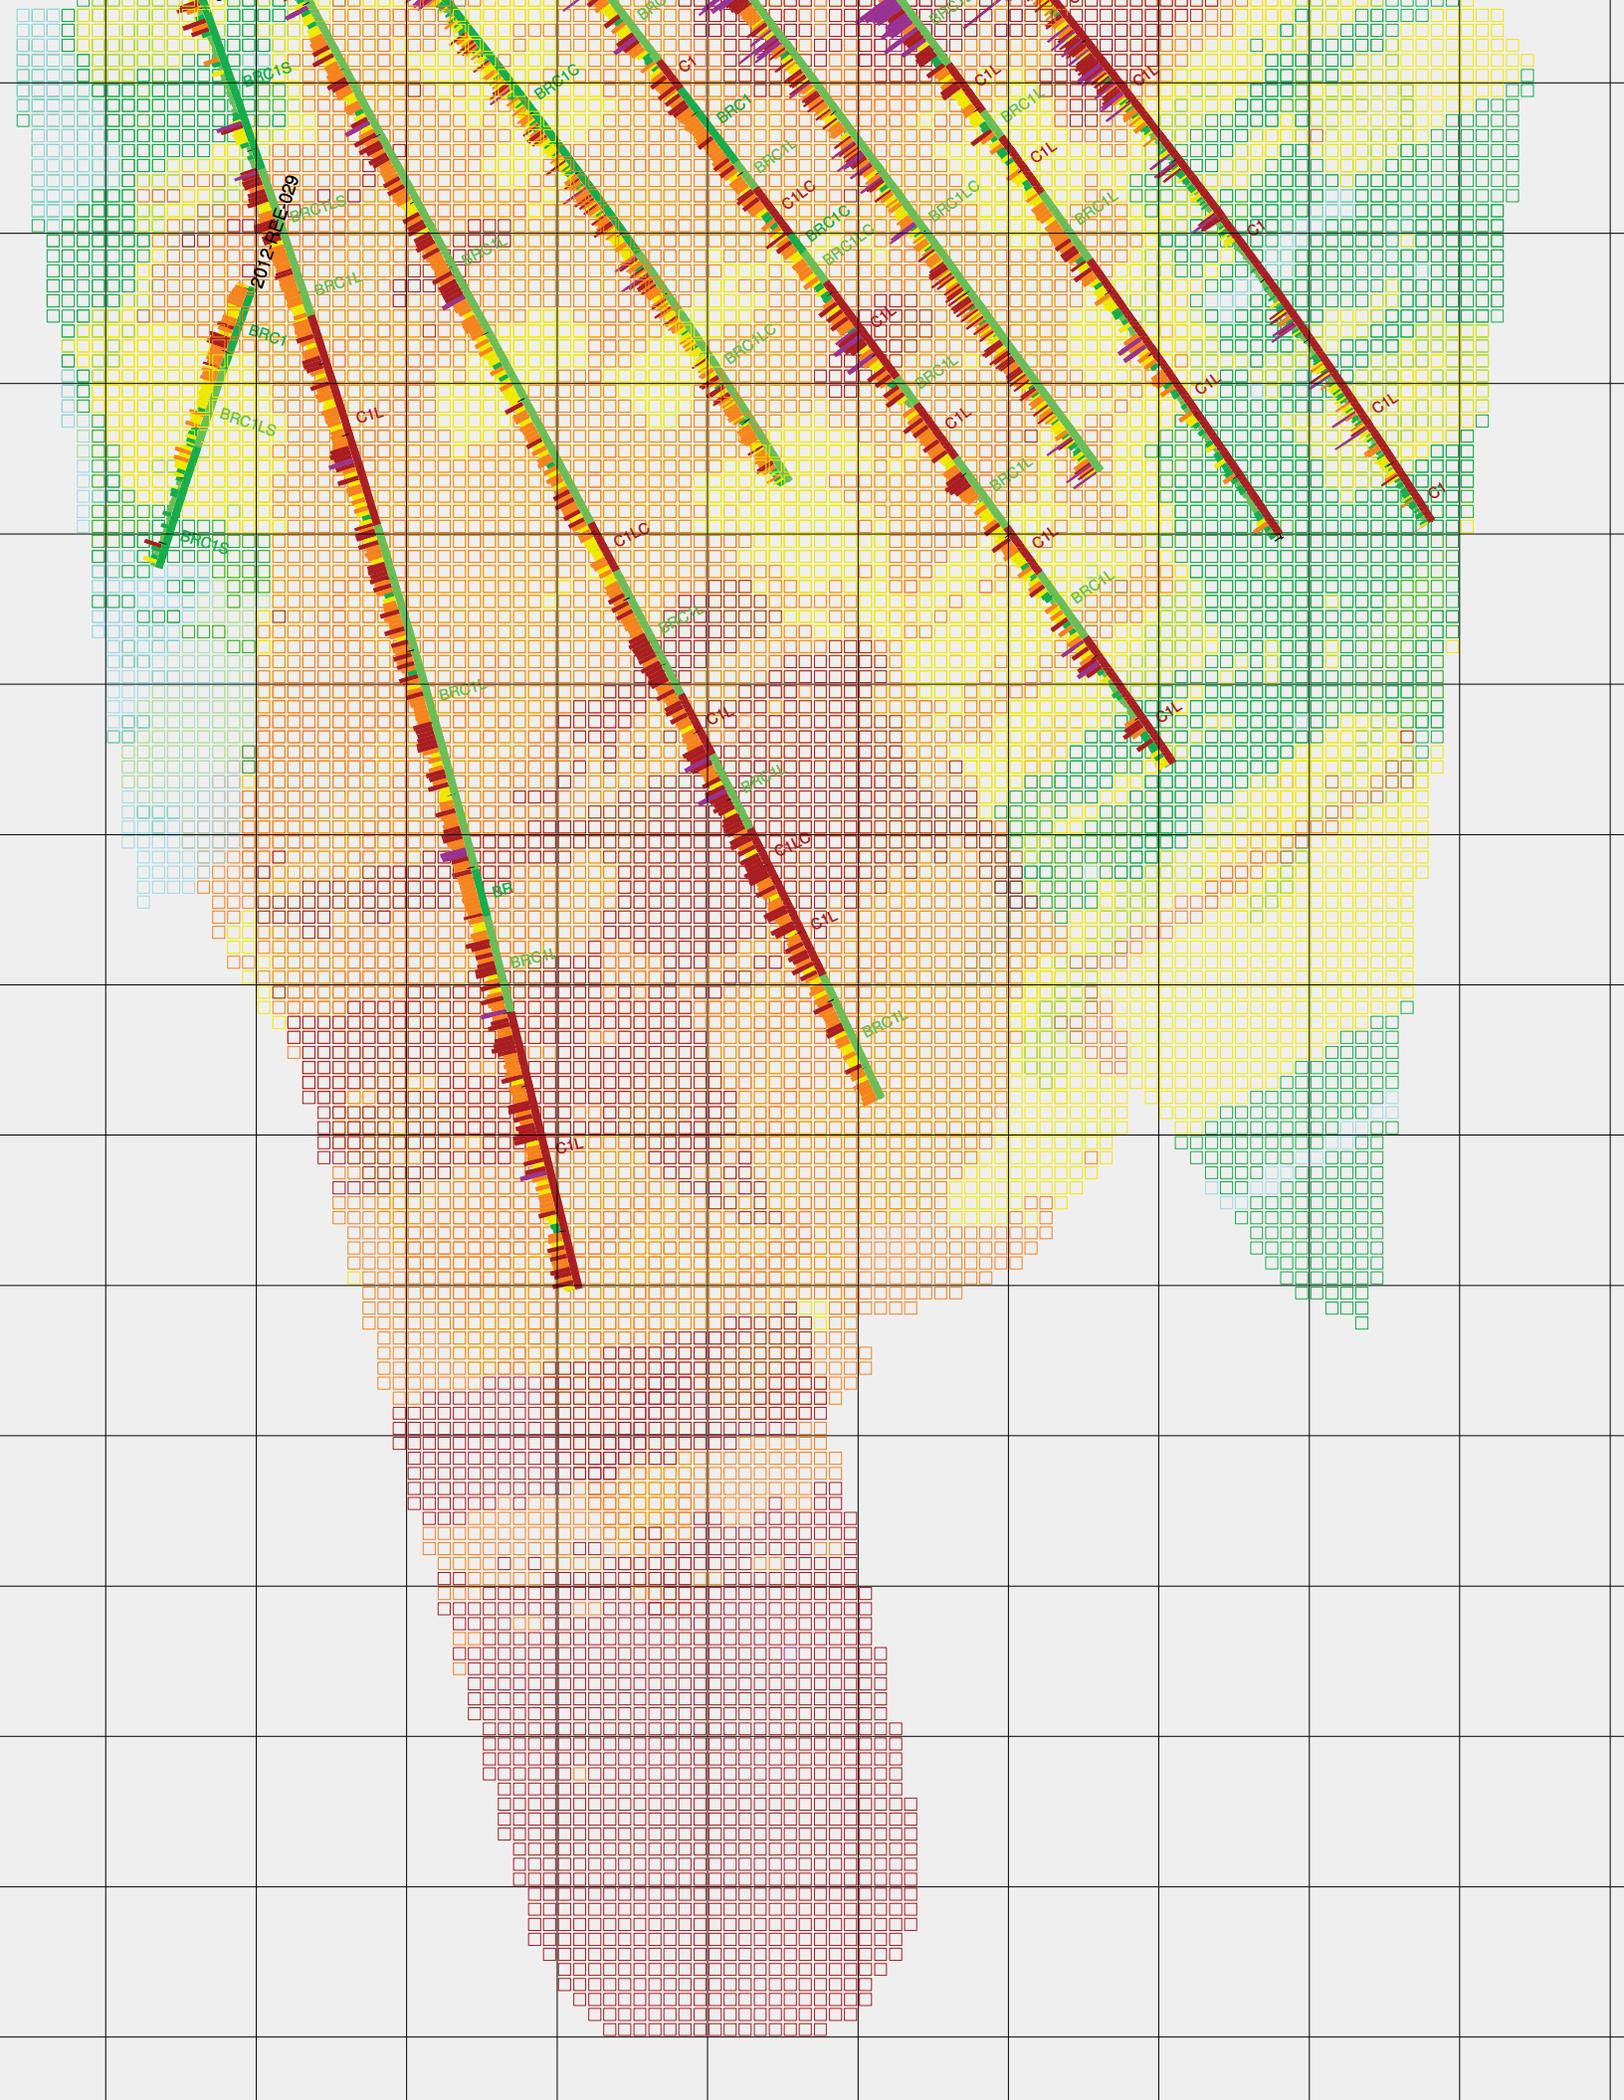

The Illustrations are included in the text.

Appendix 2: Reporting checklist

1.0 - Reporting Criteria for Sampling Techniques and Data

Item	Criteria	Essential Reporting Queries	Reserve Reporting Standards Reference	Sign Off/Comment
1.1	Sampling Techniques	Has the nature and quality of sampling (e.g. cut channels, random chips, etc) and measures taken to ensure sample representativeness been noted?	CIM- (43-101-Item 14) JORC- (Sect A: Criteria 1) SAMREC- (Sect A: Criteria 4) SME- (Criteria B.3)	Yes, Item 13 and 14, LG, JFT
1.2	Drilling Techniques	Has the drill type used (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka etc.) and the details of this drilling (e.g. core diameter, triple or standard tube, depth of diamond tails, face sampling bit or other type, whether core is oriented and if so, by what method, etc.) been specified?	CIM-(43-101-Items 13& 14) JORC- (Sect A: Criteria 2) SAMREC- (Sect A: Criteria 1) SME- (Criteria B.3)	Yes, Item 13 LG, JFT
1.3	Drill Sample Recovery	Were the core and chip sample recoveries properly recorded and results assessed?	CIM-(43-101-Item 14) JORC- (Sect A: Criteria 3) SAMREC- (Sect A: Criteria 3) SME- (Criteria B.3)	Yes, Item 14, the recovery is recorded in Gemcom databases and all the core is photographed LG, JFT
		Were measures taken to maximize sample recovery and ensure representative nature of the samples?		Yes, Item 13 and 14, the sample recovery is checked during the drilling and logging LG, JFT
		Is there a relationship between sample recovery and grade and has sample bias occurred due to preferential loss/gain of fine/coarse material?		The recovery is excellent and there is no relationship between sample recovery and the REE grade. LG, JFT
1.4	Logging	Have core and chip samples been logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies?	CIM-(43-101-Item 14)	Yes, Item 14, complete logging information are recorded in Gemcom databases

		Is logging qualitative or quantitative in nature? Is there systematic core (or costean, channel, etc.) photography?	JORC- (Sect A: Criteria 4) SAMREC- (Sect A: Criteria 2) SME-(Criteria B.3)	LG, JFT Yes, Item14, the logging is qualitative (geological unit) and quantitative (mineralization, alteration, structures). The core is photographed and stored in special folders on the computer. The core photos are linked with the Acces database into Gems LG, JFT
1.5	Sub-sampling techniques and sample preparation	If core, has it been cut or sawn and was it done in quarters, halves or was all core taken?	CIM-(43-101-Item 15) JORC- (Sect A: Criteria 5) SAMREC- Sect A: Criteria 5 SME-(Criteria B.3)	Yes, Item 14, core is systematically sawed in halves (one sent for assaying the other kept for reference material or metallurgical testing). LG, JFT N/A LG, JFT
		If non-core, has it been riffled, tube sampled, rotary split, etc, and was it sampled wet or dry.		Yes, Item 14,
		Were the nature, quality and appropriateness of the sample preparation technique consistent for all sample types?		LG, JFT
		Were quality control procedures adopted for all sub-sampling stages to maximize representativeness of samples?		Yes, Item 14-15 and 16 LG, JFT
		Were measures taken to ensure that the sampling is representative of the in situ material collected?		Yes, paragraph 11 to 13 JFT
		Were sample sizes appropriate to the grain size of the material being sampled?		Yes LG, JFT
1.6	Quality of assay data and laboratory tests	Has the nature, quality and appropriateness of the assaying and laboratory procedures used been noted along with whether the technique used is considered partial or total.	CIM-(43-101-Item 15) JORC- (Sect A: Criteria 6)	Yes, Item15 LG, JFT

		Were the nature of the quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) of acceptable levels of accuracy (i.e. lack of bias) and precision?	SAMREC-(Sect A: Criteria 6) SME-(Criteria B.3)	Yes, Item 14-15 and 16 LG, JFT
1.7	Verification of sampling and assaying	Was there verification of significant intersections by either independent or alternative company personnel?	CIM- (43-101-Item 16) JORC- (Sect A: Criteria 7)	No LG, JFT
		Was there any use of twinned holes?	SAMREC-(Sect A: Criteria 7) SME-(Criteria B.3)	No LG, JFT
1.8	Location of data points	Were accurate and quality surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation? (Includes the quality and adequacy of topographic control.)	CIM-(43-101-Item 12) JORC- (Sect A: Criteria 8) SAMREC-(Sect A: Criteria 8) SME-(Criteria B.2)	Yes, Item 13, the topography surveys and drillhole collars are executed by surveyors. Surveys (Reflex) are performed by the dilling contractor and controlled by the Geology Department. LG, JFT
1.9	Data spacing and distribution	Has the data spacing of exploration results been denoted?	CIM- (43-101-Item 14) JORC- (Sect A: Criteria 9)	Yes, Item, 13, LG, JFT
		Is the data spacing and distribution sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied?	SAMREC-(Sect B: Criteria 9) SME-(Criteria B.2)	Yes, Item 13 and 19 LG, JFT
		Has sample compositing been applied?		Yes, Item 19 LG, JFT
1.10	Orientation of data in relation to geological structure	Does the orientation of sampling achieve unbiased sampling of possible structures and has the extent to which this is known been denoted (considering the deposit type)?	CIM- (43-101-Items 13&14) JORC- (Sect A: Criteria 10)	Yes, Item9-13 and 19, the data collect respect the homogeneity of the ore body. LG, JFT
		[If the relationship between the drilling orientation and the orientation of key mineralized structures is considered to have introduced a sampling bias, this should be assessed and reported if material.]	SAMREC-(Sect B: Criteria 5) SME-(Criteria B.2)	No LG, JFT

1.11	Audits or Reviews	Are there results of any audits or reviews of sampling techniques and data?	CIM- (43-101-Items 13&14) JORC- (Sect A: Criteria 11)	No LG, JFT
		Can the date of the last independent audit be specified?	SAMREC-(Sect A: Criteria 9) SME-(Criteria B.1, B.3 & H)	No LG, JFT

2.0 - Reporting of Exploration Results

Item	Criteria	Essential Reporting Queries	Reserve Reporting Standards Reference	Sign Off/Comment
2.1	Mineral tenement and land tenure status.	Has the type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings been noted?	CIM- (43-101-Item 6) JORC- (Sect B: Criteria 1)	Yes, Item 6, LG, JFT
		Was security of the tenure held at the time of reporting along with any known impediments to obtaining a license to operate in the area noted?	SAMREC-(Sect B: Criteria 1) SME-(Criteria A.3 & A.4)	N/A LG, JFT
2.2	Exploration done by other parties	Was there any exploration done by other parties and if so, has it been acknowledged or appraised?	CIM- (43-101-Item 8) JORC- (Sect B: Criteria 2) SAMREC-(Sect B: Criteria 2,9 &10) SME-(Criteria A.2)	No, Item 8-12 and 13 LG, JFT
2.3	Geology	Has the deposit type, geological setting and style of mineralization been denoted?	CIM- (43-101-Items 7, 9, 10, 11& 17)) JORC- (Sect B: Criteria 3) SAMREC-(Sect B: Criteria 3) SME-(Criteria B.2)	Yes, Item 9 and 10 LG, JFT
2.4	Data aggregation methods	Have weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades been stated?	CIM- (43-101-Items 14, 15 & 19) JORC- (Sect B: Criteria 4)	Yes, Item 19 LG, JFT

		Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, has the procedure used for the aggregation of intercepts been stated and have some typical examples of such aggregations been provided?	SAMREC-(Sect B: Criteria 4)	Yes, Item 13 LG, JFT
		Were any metal equivalent values reported?	SME-(Criteria B.3)	Yes, Item 19, LG, JFT
2.5	Relationship between mineralization widths and intercept lengths	Is the geometry of the mineralization with respect to the drill hole angle known? (If it is not known and only the down-hole lengths are reported, there should be a clear statement to this effect.)	CIM- (43-101-Items 13&14) JORC- (Sect B: Criteria 5) SAMREC-(Sect B: Criteria 5) SME-(Criteria B.2 & C.1)	Yes, Item 13, test hole defined the circular shape of the REE zone, LG, JFT
2.6	Diagrams	Is the information being reported considered material, If so, are maps and sections (with scales) and tabulations of intercepts included to clarify the report?	CIM- (43-101-Item 26) JORC- (Sect B: Criteria 6) SAMREC-(Sect B: Criteria 6) SME-(Criteria C.1)	Yes, in the report and a complet section-plan view in annexed, LG, JFT
2.7	Balanced reporting	Where comprehensive reporting of all Exploration Results is not practicable, has the reporting been representative of both low and high grades and/or widths to avoid misleading reporting of the Exploration Results?	CIM- (43-101-Items 12&14) JORC- (Sect B: Criteria 7) SAMREC-(Sect B: Criteria 7) SME-(Criteria F.)	Yes, Item 12 and 13, LG, JFT
2.8	Other substantive exploration data	Have all other meaningful and material data been reported? [Including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.]	CIM- (43-101-Item 20)	Yes, Item 12 and 19,

			JORC- (Sect B: Criteria 8) SAMREC-(Sect B: Criteria 8) SME-(Criteria G)	LG, JFT
2.9	Further Work	Is the nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large-scale step-out drilling) known? Has it been reported?	CIM- (43-101-Item 22) JORC- (Sect B: Criteria 9) SAMREC-(Sect B: Criteria 11) SME-(Criteria.)	Yes, Item 22 LG, JFT

3.0 - Criteria for the Estimation and Reporting of Mineral Resources

Item	Criteria	Essential Reporting Queries	Reserve Reporting Standards Reference	Sign Off/Comment
3.1	Database integrity	Were measures taken to ensure that data has not been corrupted by, for example, transcription or keying errors, between its initial collection and its use for Mineral Resource estimation purposes?	CIM- (43-101-Items 15&16) JORC- (Sect C: Criteria 1)	Yes, Item 14-15 and 16, LG, JFT
		Were data validation procedures used?	SAMREC-(Sect C: Criteria 1) SME-(Criteria B.3)	Yes, Item 16 LG, JFT
		Has the level of confidence in (or conversely, the uncertainty of) the geological interpretation of the deposit been denoted?	CIM- (43-101-Items 10,11 & 21) JORC- (Sect C: Criteria 2)	Yes, Item 16-19 and 21 LG, JFT
		Has the nature of the data used, and any assumptions, been documented?	SAMREC-(Sect C: Criteria 2) SME-(Criteria C.1)	Yes, In several places in the report JFT
3.2	Geological interpretation	Is there an effect, if any, of alternative interpretations on Mineral Resource estimation?		Yes, Item 19 and 21, LG, JFT
		Was geology used in guiding and controlling Mineral Resource estimation?		Yes, Item 19, LG, JFT
		Were there any factors affecting continuity both of grade and geology?		No, LG, JFT
		Was the extent and variability of the Mineral Resource expressed as length (along strike or otherwise), plan width, and depth below surface to the upper and lower limits of the	CIM- (43-101-Item 11) JORC- (Sect C: Criteria 3)	Yes, Item 9-11-19 and 21, LG, JFT

		Mineral Resource?	SAMREC-(Sect C: Criteria 3) SME-(Criteria C.1)	
3.4	Estimation and modeling techniques	Was the nature and appropriateness of the estimation technique(s) applied reported? (Includes any assumptions regarding the treatment of extreme grade values, domains, interpolation parameters, and the maximum distance of extrapolation from data points.)	CIM- (43-101-Item 19) JORC- (Sect C: Criteria 4)	Yes, Item 19, LG, JFT
		Were check estimates, previous estimates and/or mine production records available and does the Mineral Resource estimate take account of such data?	SAMREC-(Sect C: Criteria 3) SME-(Criteria C.1 & C.2)	Yes, Item 19 and 21, previous estimate was used to compare, LG, JFT
		Were there assumptions made regarding recovery of by-products?		No, LG, JFT
		Have any deleterious elements or other non-grade variables of economic significance been estimated (e.g. sulphur for acid mine drainage characterization)?		No, LG
		In the case of block model interpolation, have the block size in relation to the average sample spacing and the search been denoted?		No, LG
		Were any assumptions made regarding modeling of selective mining units?		No, LG
		Were any assumptions made about correlation between variables?		No LG
		Have the processes used for validation, checking, and comparison of the model data to drill-hole data been reported? Did the validation process include any use of reconciliation data?		No, LG
3.5	Moisture	Were the tonnages estimated on a dry basis or with natural moisture, and has the method of determination of the moisture content been denoted?	CIM- (43-101-Item 19) JORC- (Sect C: Criteria 5) SAMREC-(Sect C: Criteria 3) SME-(Criteria C.1)	Yes, dry basis, Item 19, JFT
3.6	Cut-off parameters	Has the basis of the adopted cut-off grade(s) and/or the quality parameters applied been detailed?	CIM- (43-101-Item 19) JORC- (Sect C: Criteria 4) SAMREC-(Sect C: Criteria 4) SME-(Criteria C.2)	Yes, Item 19, LG, JFT

3.7	Mining factors or assumptions	<p>Were any assumptions made regarding possible mining methods, minimum mining dimensions and internal (or, if applicable, external) mining dilution?</p> <p>[It may not always be possible to make assumptions regarding mining methods and parameters when estimating Mineral Resources. Where no assumptions have been made, this should be reported.]</p>	<p>CIM- (43-101-Item 25)</p> <p>JORC- (Sect C: Criteria 7)</p> <p>SAMREC-(Sect C: Criteria 5)</p> <p>SME-(Criteria D)</p>	<p>No,</p> <p>LG, JFT</p>
3.8	Metallurgical factors or assumptions	<p>Were the sources for assumptions or predictions regarding metallurgical amenability clearly stated?</p> <p>[It may not always be possible to make assumptions regarding metallurgical treatment processes and parameters when reporting Mineral Resources. Where no assumptions have been made, this should be reported.]</p>	<p>CIM- (43-101-Item 18)</p> <p>JORC- (Sect C: Criteria 8)</p> <p>SAMREC-(Sect C: Criteria 6)</p> <p>SME-(Criteria D)</p>	<p>Yes, Item 18, Predictions were made from ungoing metallurgical tests,</p> <p>LG, JFT</p>
3.9	Bulk density	<p>If assumed, were the sources for bulk density assumptions clearly stated?</p> <p>If determined, was the method used clearly stated (e.g. whether wet or dry, the frequency of the measurements, the nature, size and representativeness of the samples)?</p>	<p>CIM- (43-101-Item 14)</p> <p>JORC- (Sect C: Criteria 9)</p> <p>SAMREC-(Sect C: Criteria 7)</p> <p>SME-(Criteria B.3)</p>	<p>Yes, Item 19</p> <p>LG, JFT</p>

		<p>Have all other relevant factors been taken into account and reported? (I.e. relative confidence in tonnage/grade computations, confidence in continuity of geology and metal values, quality, quantity and distribution of the data.)</p>		<p>Yes, Item 19 and 21</p> <p>LG, JFT</p>
		<p>Do the results reflect the Competent/Qualified Person(s)' view of the deposit?</p>		<p>Yes, Item 19</p> <p>LG, JFT</p>
3.11	Audits or reviews	<p>Are there any audits or reviews of the Mineral Resource estimates, and have the results been reported.</p>	<p>CIM- (43-101-Item 19)</p> <p>JORC- (Sect C: Criteria 11)</p> <p>SAMREC-(Sect C: Criteria 9)</p> <p>SME-(Criteria B.1, B.3 & H)</p>	<p>No,</p> <p>LG, JFT</p>
		<p>Has the date of the last independent audit been specified?</p>		<p>No,</p> <p>LG, JFT</p>
3.12	Discussion of relative	<p>Was a statement made regarding the relative accuracy and/or confidence in the Mineral</p>	<p>CIM- (43-101-Item 19)</p>	<p>Yes, Item 19</p>

	accuracy /confidence	Resource estimate, as well as, the approach or procedure deemed appropriate by the Competent Person? [For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors which could affect the relative accuracy and confidence of the estimate.]	JORC- (Sect C: Criteria 12)	LG, JFT
		Does the statement specify whether or not it relates to global or local estimates, and, if local, have the relevant tonnages or volumes, which should be relevant to technical and economic evaluation been stated? [Documentation should include assumptions made and the procedures used.]	SAMREC-(Sect C: Criteria 8) SME-(Criteria F)	Yes, Item 19-21, LG, JFT
		Have the statements of relative accuracy and confidence of the estimate been compared with production data, where available?		No, LG, JFT

4.0 - Criteria for the Estimation and Reporting of Ore Reserves

Item	Criteria	Essential Reporting Queries	Reserve Reporting Standards Reference	Sign Off/Comment
4.1	Mineral Resource estimate for conversion to Ore Reserves	Is there a description of the Mineral Resource estimate used as a basis for the conversion to an Ore Reserve?	CIM- (43-101-Item 19) JORC- (Sect D: Criteria 1)	No, Item 19, no reserves are reported, LG, JFT
		Is there a clear statement as to whether the Mineral Resources are reported additional to, or inclusive of the Ore Reserves?	SAMREC-(Sect D: Criteria 1) SME-(Criteria G)	Yes, Item 19 and 21, LG, JFT
4.2	Study Status	Was the type and level of study undertaken to enable the conversion of Mineral Resources to Ore Reserves denoted? [The Codes do not require that a final feasibility study be undertaken to convert Mineral Resources to Ore Reserves, but it is required that appropriate studies have been carried out to determine a mine plan that is technically achievable and economically viable, and that all Modifying Factors have been considered.]	CIM- (43-101-Item 19) JORC- (Sect D: Criteria 2) SAMREC-(Sect D: Criteria 1) SME-(Clause 13)	Yes, Item 19, Studies on the geology and recovery are underway LG, JFT
4.3	Cut-off parameters	Has the basis of the adopted cut-off grade(s) or the applied quality parameters been designated?	CIM- (43-101-Item 19) JORC- (Sect D: Criteria 3)	yes, Item 19, the cut-off grade (0.5% TREO) was used only for the volumetric calculation LG, JFT

			SAMREC-(Sect D: Criteria 3) SME-(Criteria C.2)	
4.4	Mining factors or assumptions	Have the method and assumptions used to convert the Mineral Resource to an Ore Reserve (i.e. either by application of appropriate factors by optimization or by preliminary or detailed design) been reported?	CIM- (43-101-Item 25) JORC- (Sect D: Criteria 4)	No, Item 19, LG, JFT
		Have the choice of, the nature and the appropriateness of the selected mining method(s), and other mining parameters (including associated design issues such as pre-strip, access, etc) been denoted?	SAMREC-(Sect D: Criteria 4) SME-(Criteria D)	No, Item 19, LG, JFT
		Were the assumptions made regarding geotechnical parameters (e.g. pit slopes, stope sizes, etc), grade control and pre-production drilling denoted?		No, Item 19, LG, JFT
		Were the major assumptions made as well as the Mineral Resource model used for pit optimization clearly described? (if appropriate)		No, Item 19, LG, JFT
		Were the mining dilution factors, the mining recovery factors, and the minimum mining widths used, clearly denoted?		No, Item 19 LG, JFT
		Have the infrastructure requirements of the selected mining methods been stated?		No, Item 19, LG, JFT
4.5	Metallurgical factors or assumptions	Are the proposed metallurgical processes stated, and are they appropriate to process the described style of mineralization?	CIM- (43-101-Item 18) JORC- (Sect D: Criteria 5)	No, Item 19, LG, JFT
		Are the proposed metallurgical processes well-tested technologies or novel in nature?	SAMREC-(Sect D: Criteria 7&8) SME-(Criteria D)	No, Item 19, LG, JFT
		Are the nature, amount and representativeness of metallurgical test work undertaken and the metallurgical recovery factors applied well denoted?		No, Item 19, LG, JFT
		Have any assumptions or allowances made for deleterious elements been reported.		No, Item 19, LG, JFT
		Has the existence of any bulk sample or pilot scale test work and the degree to which such samples are representative of the ore body as a whole been denoted?		Yes, Item19, LG, JFT
4.6	Cost and Revenue	Have the derivation of or assumptions made, regarding projected capital and operating	CIM- (43-101-Item 25)	No, Item 19,

	factors	costs been noted and are the assumptions and parameters used reasonable and justifiable?	JORC- (Sect D: Criteria 6)	LG, JFT
		Have the assumptions made regarding (but not limited to) revenue including head grade, metal or commodity price(s) exchange rates, transportation and treatment charges, penalties, etc, been stated?	SAMREC-(Sect D: Criteria 2, 9, 10, & 11) SME-(Criteria D & E)	No, Item 19, LG, JFT
		Are there any allowances made for royalties payable, both Government and private and have they been stated?		No, Item 19, LG, JFT
4.7	Market assessment	Have the demand, supply and stock situation for the particular commodity, the consumption trends and the factors likely to affect supply and demand into the future been denoted?	CIM- (43-101-Item 25) JORC- (Sect D: Criteria 7)	No, Item 19, LG, JFT
		Has a customer and competitor analysis along with the identification of likely market windows for the product been completed?	SAMREC-(Sect D: Criteria 5,6 & 14) SME-(Criteria E)	No, Item 19, LG, JFT
		Are there price and volume forecasts and has the basis for these forecasts been denoted?		No, Item 19, LG, JFT
4.8	Other	Are there any effects of natural risk, infrastructure, environmental, legal, marketing, social or governmental factors on the likely viability of a project and/or on the estimation and classification of the Ore Reserves?	CIM- (43-101-Item 25) JORC- (Sect D: Criteria 8)	No, Item 19, LG, JFT
		Has the status of titles and approvals critical to the viability of the project, such as mining leases, discharge permits, government and statutory approvals been verified?	SAMREC-(Sect D: Criteria 10,11,15 & 16) SME-(Criteria G)	Yes, Item 6 LG, JFT
4.9	Classification	Has the basis for the classification of the Ore Reserves into varying confidence categories been denoted?	CIM- (43-101-Item 19) JORC- (Sect D: Criteria 9)	Yes, Item 19, LG, JFT
		Does the result of the classification appropriately reflect the Competent/Qualified Person(s)' view of the deposit?	SAMREC-(Sect D: Criteria 17) SME-(Criteria C.2)	Yes, Item 19, LG, JFT
		Has the proportion of Probable Ore Reserves which have been derived from Measured Mineral Resources (if any) been denoted?		No, Item 19, LG, JFT
4.10	Audits or reviews	Have the results of any audits or reviews of Ore Reserve estimates been denoted?	CIM- (43-101-Item 19) JORC- (Sect D: Criteria 10)	Yes, Gmining, Réjean Sirois, Q1 2013 LG, JFT
		Can the date of the last independent audit be specified?	SAMREC-(Sect D: Criteria 18)	Yes, Q1 2013

			SME-(Criteria B.1, B.3 & H)	LG, JFT
4.11	Discussion of relative accuracy /confidence	Was a statement made regarding the relative accuracy and/or confidence in the Reserve estimate as well as, the approach or procedure deemed appropriate by the Competent Person? [For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the reserve within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors which could affect the relative accuracy and confidence of the estimate.]	CIM- (43-101-Item 19) JORC- (Sect D: Criteria 11)	Yes, Item 19 and 21, LG, JFT
		Does the statement specify whether or not it relates to global or local estimates, and, if local, have the relevant tonnages or volumes, which should be relevant to technical and economic evaluation been stated? [Documentation should include assumptions made and the procedures used.]	SAMREC-(Sect D: Criteria 17) SME-(Criteria F)	Yes, Item 19, LG, JFT
		Have the statements of relative accuracy and confidence of the estimate been compared with production data, where available?		No, LG, JFT

1.

2. Introduction

Ce rapport décrit en détail les opérations de terrain ainsi que toutes les étapes d'acquisition, de vérification et de traitement nécessaires pour l'obtention de données finales de haute qualité par le biais d'un levé magnétique hélicoptéré effectué par **EON Geosciences Inc. (EON)** pour **IAMGOLD Corporation (IAMGOLD)** dans les régions de Rouyn-Noranda et St-Honoré, au Québec.

En incluant les tests et calibrations préparatoires et l'acquisition des données, la réalisation du levé magnétique hélicoptéré s'est échelonnée du 3 au 15 mai 2012. Un total de 2 616 km linéaires a été nécessaire afin de couvrir la totalité des blocs Lepine, Bousquet-Odyno et Niobec.

3. Spécifications du levé

3.1. Localisation du levé

Le levé magnétique hélicoptéré, dont fait mention le présent rapport, est situé dans les secteurs de Rouyn-Noranda (blocs Lepine et Bousquet-Odyno) et de St-Honoré (bloc Niobec).

Les limites des différents blocs sont définies par les coordonnées suivantes :

Coordonnées des périmètres du levé (WGS-84)								
Lepine (UTM Zone 17N)			Bousquet-Odyno (UTM Zone 17N)			Niobec (UTM Zone 19N)		
Coin No.	X	Y	Coin No.	X	Y	Coin No.	X	Y
1	647000	5367795	1	674503	5342002	1	336642	5380106
2	657200	5367795	2	674503	5344198	2	342418	5382251
3	657200	5371094	3	676507	5344198	3	345194	5374704
4	656095	5371094	4	676508	5345305	4	339394	5372579
5	656095	5376009	5	679600	5345305			
6	647000	5376009	6	679606	5344708			
			7	681002	5344708			
			8	680997	5343007			
			9	678102	5343002			
			10	678102	5341993			

Tableau 1 : Coordonnées des zones des travaux

3.2. Topographie de la zone des travaux

Le relief dans les régions du levé est relativement plat. Plus spécifiquement, à l'intérieur des limites du levé, des valeurs topographiques qui varient entre 274 m et 379 m pour Lepine, entre 290 m et 364 m pour Bousquet-Odyno, et entre 85 m et 163 m pour Niobec, sont observées.

3.3. Spécifications de vol

3.3.1. Plans de vol

Selon les spécifications des plans de vol présentées aux Tableaux 2, 3 et 4, 2 349 km de traverses et 267 km de lignes de contrôle ont été enregistrées pour un total de 2 616 km de lignes.

	Traverses	Lignes de contrôle	Total
Espacement des lignes	75 m	600 m	
Direction des lignes	N 0° E	N 90° E	
Kilométrage	1 043 km	134 km	1 177 km

Tableau 2 : Spécifications du plan de vol – Bloc Lepine

	Traverses	Lignes de contrôle	Total
Espacement des lignes	50 m	500 m	
Direction des lignes	N 0° E	N 90° E	
Kilométrage	311 km	34 km	345 km

Tableau 3 : Spécifications du plan de vol – Bloc Bousquet-Odyno

	Traverses	Lignes de contrôle	Total
Espacement des lignes	50 m	500 m	
Direction des lignes	N 160° E	N 70° E	
Kilométrage	995 km	99 km	1 094 km

Tableau 4 : Spécifications du plan de vol – Bloc Niobec

Les déviations des plans de vol par rapport aux plans de vol théoriques (fichiers d'entrée pour la navigation) ont été analysées afin d'éliminer les portions de ligne pour lesquelles l'espacement entre deux lignes adjacentes était inférieur à 50% ou supérieur à 150% de l'espacement nominal sur une distance de plus de 2 000 mètres.

Les portions de lignes devant faire de nouveau l'objet d'un vol ont été revolées en prenant soin de respecter les exigences minimales de chevauchement telles que décrites dans les spécifications de vol du contrat.

3.3.2. Altitude de vol

Le levé magnétique hélicopté a été réalisé avec une altitude théorique de 30 m.

Afin d'assurer une différence d'altitude minimale aux intersections entre les traverses et les lignes de contrôle, et par le fait même assurer une meilleure qualité des données nivelées, une surface moulant le relief topographique a été utilisée pour la navigation. Cette surface a été calculée en considérant le relief topographique et une pente de 15%. Les données topographiques disponibles sur SRTM furent utilisées pour le calcul de la surface de vol.

Les tolérances d'altitude ont été limitées à $\pm 20\%$ de la surface de vol. De plus, cette limite de tolérance de $\pm 20\%$ fut conservée afin d'évaluer les endroits où la déviation verticale entre l'élévation GPS de l'hélicoptère et la surface de vol calculée dépassait les normes acceptables et semblait affecter les données en maille.

3.4. Spécifications techniques

Lors du contrôle de la qualité effectué quotidiennement, les spécifications techniques suivantes, telles que définies dans le contrat, en plus des spécifications de vol, ont été considérées pour la sélection des lignes ou des parties de ligne à revoler ainsi que pour l'acceptation finales des données.

3.4.1. Variations diurnes

Pour la station de base magnétique, la déviation maximale tolérée sur une longueur de corde d'une minute fut de 2,0 nT (crête à crête) sur un total cumulatif de 20% ou plus de chaque ligne de vol.

3.4.2. Niveau de bruit sur les données magnétiques

En tout temps, la 4^{ième} différence fut utilisée pour détecter et évaluer la présence de bruit sur les données magnétiques. Une enveloppe de bruit de 0,1 nT fut prise en compte pour l'acceptation finale des données.

4. Équipements utilisés

4.1. Hélicoptère

Un hélicoptère AS350BA, immatriculation C-GOVD, a été utilisé pour ce projet (Figure 1). Cet hélicoptère était équipé d'un rostre attaché au patin d'atterrissage de l'hélicoptère d'une longueur de 9 mètres permettant l'installation du capteur magnétique.

Les caractéristiques de l'hélicoptère utilisé sont les suivantes:

Type :	AS350BA
Immatriculations :	C-GOVD
Autonomie (km) :	600
Vitesse de levé (m/s) :	Moyenne de 41 (varie de 21 à 57) → Lepine Moyenne de 45 (varie de 26 à 56) → Bousquet-Odyno Moyenne de 45 (varie de 17 à 58) → Niobec
Essence :	Jet
Consommation d'essence (L/hr) :	170
Valeur pour le FOM (nT) :	2,115

5. Figure 1 : Hélicoptère (C-GOVD) utilisé pour l'exécution du levé magnétique

5.1. Systèmes aéroportés

Pour l'exécution de ses levés magnétiques héliportés, **EON** utilise des équipements à la fine pointe de la technologie tel que décrit dans les sections suivantes.

5.1.1. Magnétomètre

Un senseur Geometrics G822A, combiné à un compteur de haute résolution, a été utilisé pour mesurer les variations du champ magnétique total. Les spécifications de ce type de magnétomètre sont les suivantes :

Manufacturier :	Geometrics
Type et Modèle :	Césium G822A
Plage ambiante (nT) :	20 000 – 100 000
Sensibilité (nT) :	± 0,0005
Précision absolue (nT) :	± 3
Enveloppe de bruit (nT) :	< 0,01
Intervalle d'échantillonnage (sec) :	0,1
Effet de cap (nT) :	< 0,15

5.1.2. Système d'acquisition de données et compensateur

Le système d'acquisition et de compensation "Airborne Data Acquisition & Adaptive Aeromagnetic Real-Time Compensation (DAARC500)" de RMS Instruments a été utilisé par **EON**. Ce système permet un taux d'échantillonnage de 10 Hz (0,1 sec) et utilise un magnétomètre « fluxgate » à trois axes afin de suivre la position et les mouvements de l'hélicoptère par rapport au champ magnétique ambiant et d'ainsi calibrer la compensation selon une série de manœuvres standards de « roll », « pitch », et « yaw » dans les directions du levé.

Les entrées analogues et sérielles sont échantillonnées au même taux, ou à un sous-multiple, que les données du magnétomètre. Les données géophysiques et les données de positionnement GPS brutes sont enregistrées dans des fichiers binaires avec des marqueurs de temps et d'événement de début qui permettent une corrélation simple avec les autres données et le signal PPS du récepteur GPS. Le système d'acquisition est synchronisé au temps GPS par un signal GPS d'une seconde (PPS). Puisque la position GPS et l'UTC sont liés au « pulse » GPS, une corrélation précise est maintenue.

Ce système fournit une sortie graphique de haute résolution à un écran couleur intégré qui permet le suivi en temps réel de l'acquisition des données par l'opérateur.

5.1.3. Système de navigation

Le tableau suivant décrit le système de navigation ainsi que le système GPS différentiel héliporté utilisés pour la navigation en temps réel et l'enregistrement de la trajectoire de vol :

Système GPS différentiel héliporté	
Manufacturier :	NovAtel
Modèle :	ProPak-V3
Système différentiel temps-réel :	WAAS
Système différentiel post-mission :	PPP
Fréquences :	L1-L2
Précision (m) :	± 1
Nombre de canaux :	12

Système de navigation : Ag-Nav Linav
Affichage pour pilote : ACL avec indicateurs «up/down» et «left/right»
Intervalle d'échantillonnage (sec) : 1

Les principales caractéristiques du système de navigation sont les suivantes:

- 1) Affichage graphique du plan et de la trajectoire de vol à partir des données GPS différentielles en temps réel;
- 2) Navigation verticale utilisant une surface mouvant le relief topographique (LiNav-3D);
- 3) Indicateurs d'écarts par rapport à la ligne suivie et indicateurs de distance effectuée et à faire, indicateurs d'écarts verticaux par rapport à la surface suivie;
- 4) Modes d'opération en carte, points de destination *waypoint* ou selon des lignes planifiées;
- 5) Enregistrement des données GPS brutes pour traitement post-mission.

5.1.4. Altimètre radar

Les principales caractéristiques de l'altimètre radar installé dans l'hélicoptère sont les suivantes:

Manufacturier : FreeFlight Systems
Modèle : TRA-3000
Plage (pi) : 40 – 2 500
Précision : ± 5 pi (0-100 pi)
± 5% (100-500 pi)
± 7% (500-2500 pi)
Intervalle d'échantillonnage (sec) : 0.1

5.1.5. Altimètre barométrique

L'altitude barométrique a été calculée des données de pression et de température acquises en vol. Le tableau suivant décrit les caractéristiques des senseurs de pression et de température utilisés pour ce levé :

Manufacturier :	Vaisala	Vaisala
Modèle :	PTB110	HMP155
Paramètre mesuré :	Pression atmosphérique	Température ambiante
Précision:	± 0,3 hPa (mbar)	± 0,17 °C
Intervalle d'échantillonnage (sec) :	0.1	0.1

5.2. Station de contrôle au sol

5.2.1. Magnétomètre

Une station de contrôle au sol du champ magnétique (voir les caractéristiques ci-dessous) fut installée à chaque base (Rouyn-Noranda et St-Honoré) afin d'enregistrer sans interruption les variations diurnes.

Manufacturier :	GEM Systems
Type :	Overhauser
Modèle :	GSM-19
Plage dynamique (nT) :	15 000 – 120 000
Sensibilité (nT) :	± 0,001
Précision absolue (nT) :	± 0,1
Intervalle d'échantillonnage (sec) :	1
Niveau de bruit (nT) :	< 0,1 nT

5.3. Système utilisé pour le contrôle de la qualité

Durant les opérations de terrain, la vérification quotidienne des données, provenant des tests et calibrations ou du levé magnétique, a été réalisée en utilisant les composantes suivantes.

Ordinateurs portables :	Pentium PCs
Logiciel :	Geosoft Oasis montaj
Transmission des données :	Site FTP

6. Personnel

Le personnel d'**EON** ayant participé au bon déroulement du projet est présenté dans le Tableau 5 ci-dessous :

Opérations de terrain	
Gestionnaire de projet	Khaled Moussaoui Abbas Moussaoui
Gestionnaire de terrain/Géophysicien Contrôleur de la qualité sur le terrain	Rick Bailey
Pilote	Stéphane Caron
Responsable des instruments	Paul Beaubien
Ingénieur de l'entretien	Hélicoptères Panorama
Traitement des données	
Traitement des données finales	Rick Bailey Gérard Tessier
Produits finaux	
Préparation des cartes	Marc Richard
Rapport final	Khaled Moussaoui Rick Bailey

Tableau 5 : Personnel impliqué dans le projet

7. Opérations de terrain

7.1. Bases des opérations

Pour les blocs Lepine et Bousquet-Odyno, la ville de Rouyn-Noranda fut utilisée comme base des opérations. L'aéroport de Rouyn-Noranda a offert tous les services nécessaires, incluant l'essence Jet et la planification de vols. Pour le bloc Niobec, la ville de St-Honoré fut utilisée comme base des opérations. L'aéroport de St-Honoré a offert tous les services nécessaires, incluant l'essence Jet et la planification de vols.

7.2. Calendrier

Le Tableau 6 qui suit, présente le déroulement des différentes étapes du projet incluant les tests et les calibrations ainsi que la mobilisation et démobilitation. L'acquisition des données fut complétée le 15 mai 2012, pour un total de 2 616 km.

Hélicoptère	Date	Description
AS350BA (C-GOVD)	1 – 2 mai 2012	Installation des équipements dans l'hélicoptère à Alma
	2 – 3 mai 2012	Tests pré-mobilisation
	3 mai 2012	Mobilisation à Rouyn-Noranda
	3 mai 2012	Tests pré-levé
	4 – 5 mai 2012	Acquisition des données du bloc Lepine
	6 mai 2012	Acquisition des données du bloc Bousquet-Odyno
	7 mai 2012	Mobilisation à St-Honoré
	7 mai 2012	Tests pré-levé
	9 – 15 mai 2012	Acquisition des données du bloc Niobec
	15 mai 2012	Fin du levé / Démobilisation

Tableau 6 : Calendrier des étapes du projet

7.3. Défis opérationnels

La réalisation du levé magnétique héliporté a nécessité une collaboration et une communication constantes avec **IAMGOLD**, afin de coordonner les opérations avec les municipalités locales.

L'acquisition des données magnétiques fut interrompue principalement par les restrictions de vol au-dessus de la municipalité de St-Honoré (fins de journée et fins de semaines). De plus, les conditions météorologiques difficiles ont causé quelques journées de production perdues.

Tous ces problèmes sont détaillés dans le rapport quotidien présenté en Annexe C.

7.4. Tests et calibrations

Avant de débiter l'acquisition des données magnétiques, les tests et calibrations suivants ont été exécutés par l'hélicoptère en utilisant l'équipement décrit à la section 3.

- "Figure of Merit" (FOM)
- Étalonnage des altimètres

Les résultats détaillés de ces tests sont présentés en Annexe A.

8. Traitement des données

L'objectif principal du levé était l'acquisition et le traitement des données hélicoptées magnétiques. Le traitement préliminaire des données sur le terrain ainsi que le traitement final des données furent entièrement exécutés avec le logiciel Oasis montaj de Geosoft.

8.1. Projection cartographique

Les projections suivantes ont été utilisées pendant le projet (navigation, traitement des données, préparation des cartes) :

- Projection : UTM Zone 17N (Lepine et Bousquet-Odyno)
UTM Zone 19N (Niobec), MTM Zone 7 pour les mailles et cartes finales
- Type : Transverse Mercator
- Datum : WGS-84
- Ellipsoïde de référence : WGS-84
- Transformation locale : WGS-84 World
- Unité de longueur : Mètres

8.2. Traitement des données sur le terrain et contrôle de la qualité

À la fin de chaque vol, les données acquises étaient copiées et sauvegardées sur une unité USB, et transférées au géophysicien sur le terrain afin qu'il effectue le contrôle de la qualité et le traitement préliminaires des données tel que décrit dans ce qui suit.

En premier lieu, la trajectoire de vol était vérifiée afin de s'assurer que les lignes volées respectaient les exigences du contrat, espacement des lignes de vol, chevauchement advenant des portions de lignes ou des reprises de ligne, extension à l'extérieur du levé, etc. Une vérification de la couverture était réalisée et le kilométrage accepté était calculé et noté dans le rapport journalier de vol.

Par la suite, chacun des canaux de données enregistrés était affiché en profil, puis mis en maille, afin de vérifier que les spécifications mentionnées au contrat étaient respectées et afin de détecter rapidement d'éventuels problèmes au niveau du système d'acquisition ou de l'instrumentation. Une analyse statistique était également réalisée afin d'identifier les valeurs erronées et compléter ainsi le contrôle de la qualité.

À ce stade, toute ligne ou tout segment de ligne pouvant nécessiter un re-vol était noté. Un nivellement préliminaire était régulièrement exécuté de façon à évaluer l'impact de ces segments de lignes sur la qualité générale du produit final. Spécifiquement, la couverture, les déviations du plan et de la surface de vol, l'activité diurne, le niveau de bruit sur les données magnétiques, et les problèmes opérationnels (tel que le manque de données) sont vérifiés et les reprises de vol ensuite identifiées. Toutes les données finales ont respecté les spécifications du contrat.

8.3. Données de positionnement

Les données de positionnement RT-DGPS étaient transmises en temps réel à partir de l'unité GPS ProPak-V3 (NovAtel) vers le système d'acquisition DAARC500 pour synchronisation, enregistrement et navigation horizontale/verticale. Les corrections différentielles captées en temps réel par l'unité ProPak-V3 provenaient du système WAAS. Un contrôle quotidien de la qualité des données RT-DGPS était effectué de façon à s'assurer que leur précision demeurerait appropriée pour fins de navigation (<5 m).

Les données GPS brutes enregistrées en vol ont été utilisées dans le traitement post-mission du positionnement (PP-DGPS), en utilisant le système CSRS-PPP disponible sur le site web de Ressources naturelles Canada, afin d'obtenir des données de positionnement GPS finales en moins de quatre (4) heures. Le contrôle de la qualité final du GPS incluait l'inspection des profils de vitesse PP-DGPS ainsi qu'une comparaison avec les données RT-DGPS et d'altitude barométrique, de façon à s'assurer de l'amélioration de la précision en PP-DGPS (<1 m). Les données PP-DGPS furent de haute qualité et ne nécessitèrent aucune correction pour sauts ponctuels.

Les données de positionnement finales sont sans exception de type PP-DGPS. Elles furent utilisées pour le contrôle final du suivi de la trajectoire de vol planifiée, pour le contrôle de la qualité et l'édition des données radar via le calcul d'un modèle numérique de terrain, ainsi que pour le calcul des différences d'altitude aux intersections. Cette procédure a permis un contrôle additionnel du GPS, des données radar plus fiables, ainsi qu'une détection précise des segments de ligne présentant des déviations excessives pouvant justifier un re-vol, si la qualité des données en maille s'en trouve affectée.

8.4. Données altimétriques et modèle numérique de terrain

Tel que mentionné à la section précédente, le contrôle de la qualité sur le site et la correction finale des données radar ont été réalisés à partir du calcul d'un modèle numérique de terrain (DEM) utilisant l'altitude finale PP-DGPS et sa comparaison avec le modèle topographique publié par SRTM.

Les corrections requises sur les données radar ont été déterminées comme suit :

- Corrections distinctes des données ponctuelles erronées (*spikes*) et des sauts de niveau;
- Correction initiale, basée sur le nivellement des intersections DEM entre les lignes traverses-contrôles, visant le retrait des dérives radar à basse fréquence;
- Nivellement brut DEM basé sur un filtre de 0,6 sec appliqué sur les données radar et la décorrugation directe de la maille DEM résultante.

Les données radar finales ont été maillées en utilisant uniquement les lignes de traverse et une cellule de maillage de 10 m (pour Bousquet-Odyne et Niobec) et de 15 m (pour Lepine), en utilisant l'algorithme de courbure minimale du logiciel Oasis montaj de Geosoft.

8.5. Données aéromagnétiques

Les données magnétiques provenant de la station de contrôle au sol étaient analysées quotidiennement afin de s'assurer qu'aucune donnée en vol n'ait été enregistrée durant des périodes présentant des micro-pulsations ou de l'activité diurne excédant les spécifications. Bien que toutes les précautions aient été prises afin d'installer la station de base dans des zones magnétiquement calmes, loin de toute activité humaine, passage de véhicules, lignes de transmission ou autre, les données magnétiques des stations de base furent également vérifiées afin de noter, et corriger s'il y a lieu, tout signal d'origine culturelle.

La correction du signal magnétique dû à la direction et aux manœuvres de l'hélicoptère fut effectuée durant l'acquisition via une compensation en temps réel utilisant les coefficients de compensation calculés lors des tests de FOM. Tel que mentionné auparavant dans la section 5.4, les résultats détaillés de ces tests sont présentés en Annexe A. La compensation en temps réel permet également le contrôle de la qualité des données par l'opérateur, lui permettant ainsi d'établir si les turbulences ou autres conditions de vol sont nuisibles à la qualité des données et par le fait même, déterminer si l'arrêt du vol en cours est nécessaire.

Après application d'une correction de décalage sur les données du champ magnétique total compensées, les données en profil furent vérifiées sur une base quotidienne afin d'évaluer l'efficacité de la compensation. Par la même occasion, une quatrième différence fut calculée à partir des données du champ magnétique total compensé afin de déterminer le niveau de bruit et de procéder à l'édition des

données en profil, où les données ponctuelles erronées (*spikes*) ont été éliminées.

Dans le but d'éliminer les variations diurnes des profils de données magnétiques enregistrées en vol, une correction diurne fut calculée en utilisant les profils de la base éditée. La correction diurne fut obtenue par la soustraction d'une valeur moyenne de 55 979,9 nT (pour Lepine et Bousquet-Odyno) et de 55 586,9 nT (pour Niobec), et par l'application subséquente d'un filtre spatial *1-D FFT Butterworth* de 1 200 m. La longueur du filtre fut déterminée selon l'espacement des lignes de contrôle et le degré d'amélioration observé suite à la correction sur les différences du champ magnétique aux intersections.

Un signal IGRF partiel fut ensuite utilisé afin de minimiser l'effet des déviations de la surface de vol entre lignes adjacentes. Les champs IGRF 2010 furent premièrement calculés pour les surfaces de vol. Un filtre passe-bas de 5 sec fut ensuite appliqué. Puis, le signal IGRF partiel fut calculé et enlevé du champ magnétique total (TMF) édité pour obtenir un TMF corrigé pour l'altitude.

La prochaine étape du traitement du TMF fut le nivellement, qui consiste à la distribution statistique appropriée des erreurs d'intersections traverses-contrôles, afin d'obtenir le modèle de correction le plus lisse possible sur chaque ligne. Un modèle de correction simple initial (moyenne) est premièrement appliqué sur les lignes de contrôle, et ensuite sur les lignes de traverse après avoir mis à jour les intersections sur les lignes de contrôle corrigées. Ce processus est poursuivi de façon itérative, utilisant des modèles de correction de longueur d'onde progressivement décroissante, afin de corriger davantage les erreurs résiduelles des passes précédentes. Les modèles de correction finaux ont été basés sur une *spline* à tension, avec tension = 0,0 et aspect lisse = 0,1 (traverse), tel que permis par le réseau des lignes.

Du micro-nivellement, un processus basé sur l'application de filtres en maille directionnels, a été exécuté, afin d'enlever les corrugations sur le TMF résiduel nivelé (visibles sur la première dérivée) observées surtout dans les intervalles de traverse entre les lignes de contrôles. De telles corrections furent inévitables dus, en partie, au ratio de réseau 10:1/8:1, mais surtout aux grandes déviations en altitude de la surface de vol tel que requis au-dessus des zones habitées. Les corrugations sont souvent les plus fortes dans des régions de haut gradient magnétique. Comme tel, un processus de micro-nivellement à deux (2) passes est appliqué. Les deux (2) passes utilisent un seuil limite variable pour minimiser l'application de filtres dans les zones où le nivellement par intersection est efficace. La première passe est contrôlée par la déviation en altitude de la surface de vol, tandis que la deuxième passe est contrôlée par l'activité relative du bloc, utilisant le signal analytique du TMF nivelé. Les paramètres de contrôle et de seuil limite sont spécifiés dans le Tableau 7 ci-dessous.

Bloc	Longueur du filtre en maille (m)	Longueur du filtre en profil (m)	Passe 1 Déviation de la surface de vol (m)	Seuil limite (nT)	Passe 2 Signal analytique (nT)	Seuil limite (nT)
Lepine	450	300	-6 à 6	7	<2,0	7
			-10 à -6 et 6 à 10	Interpolation linéaire 7 à 50	2,0 à 3,0	Interpolation linéaire 7 à 50
			<-10 ou >10	50	>3,0	50
Bousquet-Odyno	250	250	-6 à 6	5	<1,0	0
			-10 à -6 et 6 à 10	Interpolation linéaire 5 à 25	1,0 à 1,5	Interpolation linéaire 0 à 25
			<-10 ou >10	25	>1,5	25
Niobec	250	250	-6 à 6	7	<2,0	7
			-10 à -6 et 6 à 10	Interpolation linéaire 7 à 50	2,0 à 3,0	Interpolation linéaire 7 à 50
			<-10 ou >10	50	>3,0	50

Tableau 7 : Paramètres de micro-nivellement

Le micro-nivellement dans la première passe a été appliqué en calculant la maille d'erreur sur le TMF en appliquant un filtre passe-haut *Butterworth* (se référer au Tableau 7 pour les longueurs d'onde limites, ordre=0) et un filtre cosinus directionnel (direction=180° pour Lepine et Bousquet-Odyno, direction=340° pour Niobec, degré de la fonction cosinus=1,5). La maille d'erreur est enlevée du TMF nivelé par lignes de contrôle pour produire une maille corrigée. Cette maille est ré-échantillonnée dans la base de données et le champ d'erreur est créé par la soustraction des profils nivelés par lignes de contrôle. Ce champ d'erreur est ensuite limité (seuil limite contrôlé par la déviation de la surface de vol) et un filtre passe-bas est appliqué. Ceci devient la première passe de la correction de micro-nivellement, qui est appliquée au champ magnétique nivelé par lignes de contrôle. Ce processus est ensuite répété sur le TMF micro-nivelé résultant (première passe), cette fois utilisant le signal analytique comme contrôle pour le degré de limitation. La correction totale de micro-nivellement est l'addition des deux (2) passes.

Finalement, le champ géomagnétique de référence (IGRF) fut calculé selon le modèle IGRF-2010 en utilisant une date fixe, la position d'acquisition et une altitude de vol moyenne fixe, pour chaque bloc. Les paramètres de correction IGRF sont spécifiés dans le Tableau 8 ci-dessous. Le champ magnétique total résiduel fut obtenu par la soustraction du champ géomagnétique de référence du champ magnétique total micro-nivelé.

Bloc	Altitude IGRF (m)	Date IGRF
Lepine	342,5	2012/05/04
Bousquet-Odyno	348,2	2012/05/06
Niobec	163,0	2012/05/12

Tableau 8 : Paramètres de correction IGRF

6.4.3. Données maillées

Les données magnétiques finales ont été maillées en utilisant uniquement les lignes de traverse et une cellule de maillage de 10 m (pour Bousquet-Odyno et Niobec) et de 15 m (pour Lepine), en utilisant l'algorithme de courbure minimale du logiciel Oasis montage de Geosoft. Le calcul de la dérivée première verticale a été réalisé en utilisant la fonction *magmap1* de ce logiciel.

9. Produits finaux

9.1. Particularités de la compilation

Échelle des cartes :	1:10 000 (Lepine et Niobec) 1:5 000 (Bousquet-Odyno)
Coordonnées (WGS-84) :	UTM Zone 17N (Lepine et Bousquet-Odyno) UTM Zone 19N (Niobec), MTM Zone 7 pour les mailles et cartes finales
Quadrillage des mailles :	15 mètres (Lepine) et 10 mètres (Bousquet-Odyno et Niobec)

9.2. Cartes finales

Les cartes finales suivantes ont été remises à **IAMGOLD** en deux (2) copies papier :

- Le champ magnétique total (avec et sans contours)
- Le champ magnétique total résiduel (avec et sans contours)
- La dérivée première verticale du champ magnétique total
- La trajectoire de vol

9.3. Données numériques

Les données numériques suivantes ont été livrées à **IAMGOLD** en trois (3) exemplaires sur DVD :

Résumé des produits numériques finaux		
Produit	Données	Format et projection
Bases de données	Données magnétiques	Geosoft GDB, WGS-84
Mailles	Champ magnétique total	Geosoft GRD, WGS-84
	Champ magnétique total résiduel	Geosoft GRD, WGS-84
	Dérivée première verticale du champ magnétique total	Geosoft GRD, WGS-84
Cartes 1:50 000	Champ magnétique total (avec et sans contours)	Geosoft MAP et PDF, WGS-84
	Champ magnétique total résiduel (avec et sans contours)	Geosoft MAP et PDF, WGS-84
	Dérivée première verticale du champ magnétique total	Geosoft MAP et PDF, WGS-84
	Trajectoire de vol	Geosoft MAP et PDF, WGS-84
Rapport	Logistique, traitement et documentation des produits	WORD et PDF

Une description complète des bases de données finales est fournie en Annexe B.

9.4. Autres produits

- Trois (3) copies papier du rapport final

10. Conclusion

L'acquisition des données magnétiques hélicoptées des blocs Lepine, Bousquet-Odyno et Niobec, situés dans les régions de Rouyn-Noranda et St-Honoré, a été complétée en utilisant un hélicoptère AS350BA, C-GOVD, permettant la mesure du champ magnétique total, grâce à un magnétomètre monté dans un rostre fixé au patin d'atterrissage de l'hélicoptère.

Une fois mobilisé sur le site des travaux, environ deux (2) semaines ont été nécessaires pour acquérir les 2 616 km linéaires de données magnétiques.

Les problèmes majeurs rencontrés lors de ce levé, qui ont quelque peu ralenti la production, sont les restrictions de vol au-dessus de la municipalité de St-Honoré et les mauvaises conditions météorologiques. La totalité des données acquises respecte les exigences d'**IAMGOLD** et a permis la production de produits finaux de haute qualité.

12. Annexe B – Description des champs des bases de données finales

12002 – Lepine, Bousquet-Odyno, Niobec – Quebec, Canada 2012
 Final database (June 7th 2012)
 EON Geosciences Inc.
 Rick Bailey

Notes: -All data were acquired from Astar 350 BA aircraft, registration C-GOVD, (RMS acquisition system).
 -Data channels were kept at their original field sampling rates.
 -Lags have been applied to raw and processed data channels, unless otherwise specified.
 -See processing notes below.

Channel description (1-21) :

	Channel Name	Sampling Rate	Units	Description	Comments
1	Line10	10Hz		Line Number	
2	Lon	01Hz	deg	Longitude	
3	Lat	01Hz	deg	Latitude	
4	x	01Hz	m	UTM Easting	WGS-84, Z17N(L,B)/19N(N), Differential GPS
5	y	01Hz	m	UTM Northing	WGS-84, Z17N(L,B)/19N(N), Differential GPS
6	fid10	10Hz	s	Fiducial Time	UTC seconds past midnight
7	hgps	01Hz	HH:MM:SS.SS	Time	
8	raltlc	10Hz	m	Radar altitude, edited	AGL, corrected for spikes, noise, adjusted through DTM levelling
9	z	01Hz	m	GPS altitude	MSL, from Differential GPS
10	DTMC	01Hz	m	Digital Topographic Model, edited	Calculated from the difference between z, raltlc and the gps antenna - altimeter offset. MSL
11	baseA	01Hz	nT	Base A TMF	Mag base station, edited
12	m31	10Hz	nT	TMF	Lag removed
13	mreslc	10Hz	nT	TMF, partial IGRF removed	Partial IGRF to drape surface removed from m31
14	mreslcb	10Hz	nT	TMF, diurnals corrected	Filtered diurnal signal removed from mreslc
15	mreslvl	10Hz	nT	TMF, levelled	Intersection levelling correction applied on mreslcb
16	mreslvli	10Hz	nT	TMF, levelled, IGRF removed	IGRF removed from mreslvl
17	mreslvld2	10Hz	nT	TMF, micro-levelled	Micro-levelling correction applied on mreslvl
18	mreslvld21	10Hz	nT	TMF, micro-levelled, IGRF removed	IGRF removed from mreslvld
19	migrfz2	10Hz	nT	IGRF	Applied IGRF Field
20	x_MTM	01Hz	m	MTM Easting	WGS-84, MTM Zone7, Niobec only
21	y_MTM	01Hz	m	MTM Northing	WGS-84, MTM Zone7, Niobec only

Processing Notes :

1. Base station data were manually edited for cultural interference.
2. A 'height correction' based on IGRF was applied to account for height deviations from drape.
3. IGRF was removed after levelling.
4. Corrugation still remains between ties after tie-line levelling. As a result, two passes of micro-levelling were used. Both passes use a variable clip to minimize filtering in areas where intersection levelling is effective. In pass 1, the degree of micro-levelling is limited by altitude deviation from drape, while pass 2 is limited by the relative activity of the block, using the analytic signal of mreslvd1. See Table I below for processing parameters.
5. IGRF is calculated at a fixed average survey height on a fixed date (Table I).

PROCESSING PARAMETERS (Table I) :

Block	Grid Filter Length (m)	Pass 1 - Deviation from drape (m)	Clip (nT)	Pass 2 - Analytic Signal (nT)	Clip (nT)	IGRF Altitude (m above MSL)	IGRF Date
1 Lepine (L)		<-10 or >10	50	<2.0	7	342.5	2012/05/04
		-6 to 6	7	2.0 to 3.0	Lin. Interp 7 to 50		
		-10 to -6 and 6 to 10	Lin interp. 7 to 50	>3.0	7		
2 Bousquet-Odyno (B)	250	<-10 or >10	25	<1.0	0	348.2	2012/05/06
		-6 to 6	5	1.0 to 1.5	Lin. Interp 0 to 25		
		-10 to -6 and 6 to 10	Lin interp. 5 to 25	>1.5	25		
3 Niobec (N)	250	<-10 or >10	50	<2.0	7	163.0	2012/05/12
		-6 to 6	7	2.0 to 3.0	Lin. Interp 7 to 50		
		-10 to -6 and 6 to 10	Lin interp. 7 to 50	>3.0	7		

GRIDS (TABLE II) :

Grid Name	Units	Comments
12002_I_TMF.grd	nT	Gridded from mreslvd2 channel (Micro-levelled total field magnetic)
12002_B_TMF.grd		
12002_N_TMF.grd		
12002_I_RTF.grd	nT	Gridded from mreslvd2i channel (Micro-levelled total field magnetic, IGRF corrected)
12002_B_RTF.grd		
12002_N_RTF.grd		
12002_I_FVM.grd	nT/m	First Vertical Derivative of mreslvd2 (Micro-levelled total field magnetic)
12002_B_FVM.grd		
12002_N_FVM.grd		

13. **Annexe C – Rapport quotidien**

EON GEOSCIENCES INC
report (C-GOVD sheet 1/1)

Aircraft
C-GOVD
Code: 12002, L
Type: ASTAR-3508A
FBO: Panoma Helicopters
Inst: Stinger/Mag

Area & Client
IAMGOLD, Lepine (Abitibi)
IAMGOLD, Bousquet-Odyno (Abitibi)
IAMGOLD, Niobec (Saguenay)

Crew chiefs: Stephane Caron
Pilots: Paul Beaubien
Engineers: Gerard Tessier, Khaled Mousseau, Richard Bailey
Processors:
